**Abstract.** The Web is rapidly becoming the prime medium for human socialization. The resources that enable that process (social web sites, blogs, media objects, etc.) present growing complexity and, collectively, weave an ever more intricate web of relationships. Current technology for declaring those relationships is predominantly implicit, ambiguous and semantically poor. As a consequence, their automatic assessment is complex and error prone, preventing the satisfaction of users' needs such as effective semantic searches. To address these limitations, whilst enabling the explicit declaration of semantically unambiguous relationships between digital resources, a solution employing structured semantic descriptors and ontologies was conceived, based on MPEG-21. This paper explains the functioning of the devised mechanism, and goes beyond that, into the definition of two novel employment venues for it, at the service of two real-world usage scenarios. These demonstrate the mechanism's added value as a powerful alternative for the semantically aware interconnection of web resources, and highlight the increased QoE that said mechanism enables.

**Keywords:** Semantic Web, relationships, MPEG-21, DID, DII, Cloud, QoE, Content Search, Metadata, RDF/OWL.

## 1 Introduction

The Internet was developed based on a host-centric perspective. Still, it is now evolving into a "content-centric" operating structure [2]. Within this new operational paradigm, the key elements are no longer the "hosts", but rather the exchanged data and services [1]. Availability of information concerning the relationships between such elements is fundamental to foster the successful establishment of the emerging new paradigm and of the added QoE that it brings about to Internet usage.

However, current technology enables the expression of, only, very rigid and semantically ambiguous relationships, between Internet's informational resources. For instance, the standard way of declaring a relationship between two digital documents, on

1  
2  
3  
4  
5  
6  
7 the web, is to insert, in one of them, the other one's URL. In HTML, for instance, this  
8 is done with the `<a>` or `<link>` tags.

9 New powerful and flexible mechanisms for the unambiguous expression of such re-  
10 lationships would definitively contribute to enable a semantically more precise and  
11 more automated manipulation, and navigation, of resources.

12  
13 In this context, a novel mechanism was developed by the authors, for declaring se-  
14 mantic relationships between digital resources, building upon the MPEG-21 standard.  
15 Said mechanism, whilst adopting the MPEG-21 principles by using structured de-  
16 scriptors, expands that technology through a specific use of semantic metadata ex-  
17 pressed in RDF/OWL. This novel tool provides the necessary capabilities to enable a  
18 full, and flexible, expression of the relational context of MPEG-21 Digital Items, on a  
19 domain specific basis. Validating the relevance and innovativeness of the mechanism  
20 in scope, is its acceptance as an extension to part 3 of the MPEG-21 standard [8].  
21

22  
23 This paper explains the mechanism's concept and presents two of its possible novel  
24 exploitation venues, thus demonstrating its added value. It is structured as follows:  
25 section 2 exposes the growing need for unambiguous expression of inter-resource  
26 relationships, highlighting the need for new tools to perform that expression; section 3  
27 presents the MPEG-21 DI concept and exposes its limitations for expressing the men-  
28 tioned relationships; section 4 presents the mechanism developed to overcome the  
29 identified limitations; section 5 presents two novel exploitation venues for the mecha-  
30 nism, with a special focus on its employment in a cloud-based blog support system;  
31 section 6 summarizes the overall added value of the mechanism in scope; and section  
32 7 contains the final conclusions.  
33

## 34 **2 Relationships Expression and Assessment**

### 35 **2.1 State of the Art**

36  
37  
38  
39 Current, successful, human-centric Internet-based initiatives greatly depend on their  
40 ability to efficiently exploit the relationships that bind together their user community  
41 and the resources they provide. For instance, Facebook collects and exploits friend-  
42 ship or "*Liking*" relationships that users declare; IEEEEXplore uses the cited refer-  
43 ences of science papers that authors supply; and Amazon deduces and exploits relationships  
44 between sold goods based on users' purchase patterns. The assessment of the relation-  
45 al context of real and digital resources is thus becoming a concrete necessity.  
46

47  
48 Generally speaking, two main alternative strategies exist to obtain this type of  
49 knowledge:

- 50 • implicitly, through information extraction and deduction by artificial intelligence  
51 mechanisms;
- 52 • explicitly, through the use of mechanisms that allow resource producers to insert  
53 semantically-rich inter-resource relationships.  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3  
4  
5  
6 The first strategy has great potential, as it does not depend on the existence of rela-  
7 tional metadata or on its quality. It typically employs content-based mechanisms that  
8 extract low-level features and infer relationships between analysed content [11]. How-  
9 ever this process is still costly and poorly achieved. In fact, artificial reasoning, of  
10 human-level reliability, is of dubious achievement and is difficult to verify [22].  
11

12  
13 The second strategy implies a greater investment at resource production time, for  
14 the expression of the resources' relational context. However, after that information is  
15 produced, it can be unambiguously and universally interpreted and exploited, through  
16 simple means. Currently, it is possible to find some information of this type on tags  
17 assigned by users to resources they publish or consume [10]. However, tagging infor-  
18 mation is far from being reliable and it is highly subjective and context-dependent.  
19

20  
21 The simplest way of declaring a relationship between two digital documents is to  
22 insert in one of them, the other one's URL. In HTML this is possible with the *<a>*  
23 and *<link>* tags. Such specifications include some support for the definition of the  
24 nature/type of the declared relationship. However these provide a very limited and still  
25 semantically ambiguous relationship type pool. This is why such information is sel-  
26 dom used, and generally left unexploited by browsers and search engines [12].  
27

28 The Microformats [14] approach emerged as an evolution to the concept of embed-  
29 ding machine-readable metadata into HTML pages. Recently replaced by similar  
30 stronger initiatives, such as the W3C RDFa [15] and the Google-Yahoo-Bing sche-  
31 ma.org [16], this trend, when consolidated, will allow machine parsing and under-  
32 standing of web content.  
33

34 In parallel, the Semantic Web and Linked Data [13] initiatives, strive to promote  
35 usage and supply of structured semantic information, by humans, in a manner that  
36 renders it understandable by machines. They suggest representing content in funda-  
37 mentally more structured ways than HTML. By careful usage and linkage of precise  
38 metadata, machine-assisted inference, automated information mashups and semantic  
39 search become possible and useful.  
40

41 In-line with the Linked Data initiative, the OAI-ORE standard [21] provides the  
42 means for the declaration of inter-resource relationships within resource aggregations  
43 in a semantically meaningful way.  
44

45 Although the latter proposals (W3C RDFa, Linked Data and OAI-ORE) start to  
46 weave a global, structured metadata mesh to describe real and digital resources and  
47 their relationships, their current implementation or employment levels are still at an  
48 early stage. Furthermore they are meant as an informational patch to be added to cur-  
49 rent web pages to provide semantically more precise meaning to their contents. Their  
50 employment is not organic to the objects that they are meant to enrich, resulting in,  
51 either a profuse intermixing of data and metadata (as in RDFa), or in a loss of self-

containment (as in OAI-ORE), considering that data and metadata objects are to be distributed separately.

It can thus be concluded that there is still a lack of efficient mechanisms that are able to support in a reliable and practical manner, the semantically precise expression and assessment of the relational context of real and digital resources. Such mechanisms should ensure that the diffusion of these semantic relationships is easily done in a coherent way, synchronized to that of the corresponding resources.

## 2.2 The Way Forward

The first of the above-mentioned strategies imposes greater demands and is unlikelier to obtain superior results than the latter, in the short term.

For that reason and for the fact that the focus of the work here presented, is the explicit semantic linking between self-contained digital objects, we pursue the second strategy (referred in section 2.1), for the acquisition of inter-resource relationship information.

The success of this strategy requires a comprehensive and, simultaneously, versatile tool for the structuring and description of information objects. Such a tool should enable information producers to: 1) perform a simple and semantically precise expression of inter-resource relationships; and 2) bind the descriptive data to the described objects and package and distribute this set in a reliable, transparent and coherent way.

An additional factor that contributes to the success and rapid adoption of any new technology concerns the use of open standards. Standardisation of the developed technologies is normally an added value, especially near the industry, to encourage wider take-up.

Accordingly, the approach that was adopted in this work to attain such a tool whilst taking into consideration the mentioned aspects, was to extend the MPEG-21 standard, taking advantage of domain-specific ontologies expressed using also standardized technologies, notably RDF/OWL. This tool empowers the MPEG-21 to support rich and flexible expression of relationships, between digital objects, within the context of domain specific ontologies of such relationships. This standard was chosen, over others, because, unlike them, it provides a globally coherent and extensive framework to structure and describe information objects, as well as to create self-contained packages.

With the incorporation of our solution into the MPEG-21 standard, information producers will be able to use the Digital Item (DI) concept as a structured container to declare and encapsulate all the media components of their creations, together with relevant metadata, including the digital item's relational context. As we aim at demonstrating in the following sections, this will contribute to the enhancement of the Internet as a whole, as the extended MPEG-21 standard provides useful means to enable a

1  
2  
3  
4  
5  
6  
7 more semantically aware manipulation of digital resources. Accordingly, before actually presenting the novel inter-resource relationship expression mechanism, a brief description of the MPEG-21 standard together with a detailed view on its shortcomings concerning the capability to describe a DI's relational context, is provided in the next section.

8  
9  
10  
11  
12 The remainder of the article explains the developed mechanism, which is now part of the MPEG-21 DII standard [9], demonstrating its added value in enabling MPEG-21 to address the needs identified in section 2, and goes beyond that, into the definition of two novel employment venues for it, at the service of two real-world usage scenarios.

### 18 3 MPEG-21

#### 19 3.1 Contextualization

20  
21  
22 MPEG-21 is a powerful multipurpose content declaration standard that enables the multidimensional definition, structuring and packaging of sets of media resources into metadata rich, self-contained, information objects. These are designated as "Digital Items" (DIs) [5] in MPEG-21 part 2, DID [6]. MPEG-21 DIs, within the context of MPEG-21's DID Language (DIDL), are expressed in XML and carried in Digital Item Declaration (DID) documents. The Digital Item Identification (DII) specification [8] provides the tools to uniquely identify DIs and link them to related information.

23  
24  
25  
26  
27  
28  
29  
30 We think these capabilities are extremely synergistic with the idea of extending content-centeredness to include "resources" such as real world objects, services and people, and to support the semantically precise description of their relational contexts.

#### 31 3.2 Limitations of MPEG-21 for Relational Context Definition

32  
33  
34  
35  
36  
37  
38  
39 The core technologies of the DI are the DID and the DII. However, these tools enable only a rigid, limited and generally implicit description of inter DI relationships.

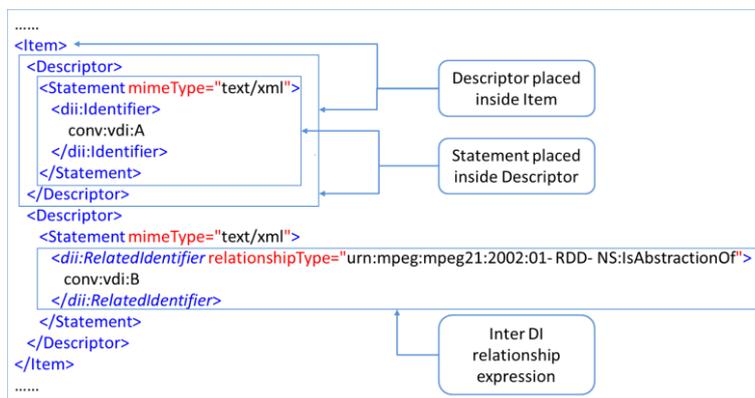

Fig. 1. Expressing Relationships in DID and DII

1  
2  
3  
4  
5  
6  
7 The DID supports only the implicit expression of containment/composition relationships between DIs by placing XML elements within elements, according to a strict linear hierarchy (as explained at the top of Fig. 1). Alternatively, DID elements may explicitly include other elements employing the XInclude [23] tool. However, XInclude only enables the specification of *inclusion* relationships, and of no other type (such as, for instance, a correction relationship as in *DI\_A corrects DI\_B*), thus being quite poor at the semantic level.

14  
15 The original DII specification enabled the explicit expression of a limited set of inter-DI relationships, through the employment of *dii:RelatedIdentifier* elements and their *relationshipType* attribute (as indicated at the bottom of Fig. 1). It was more versatile than the DID, however, it was still insufficient as a fully-fledged tool for the expression of the relationships that normally occur.

21 The standard was then extended through an amendment [7] to MPEG-21 Part 3 [8], whereby the *dii:RelatedIdentifier* element was semantically enriched with the capability to express the nature of the relationship. Still, the available pool of relationship types is very small and, though it may be extended, such extension requires the registration of the new type with the Registration Authority for ISO/IEC. This is an unpractical scheme for the definition of relationship taxonomies and is also completely divorced from the RDF/OWL universe, which would be the natural venue for the expression of the logical connections in scope.

31 The tools defined in DID and DII are thus inadequate for the expression of semantically-rich inter-DI relationships. Their use would lead to contrived metadata constructs that would be hard, or impossible, to query through common and widespread technologies such as SPARQL. Furthermore, they do not allow the expression of relationships of higher complexity such as non-binary relationships, or property endowed relationships (e.g. a relationship with an *occurrenceTime* property).

## 39 4 A Novel Semantically-rich Resource Relating Mechanism

### 41 4.1 Rationale

42  
43 In light of the conclusions drawn in the previous section, a relating mechanism was developed to allow resource creators to easily express static and explicit inter-resource relationships. It employs RDF/OWL constructs, expressed in XML, thus being aligned with the Linked Data initiative. Resources must however be expressed according to the standardized MPEG-21 DI format, as these constructs have been defined embedded in the MPEG-21 specification, in line with the analysis made in section 2.2. The following sections explain this process and the details of the mechanism.

## 4.2 Definition

In practical terms, the developed mechanism consists of the addition of a new DII element, named *dii:Relationships*, to the current specification of the MPEG-21 DII standard.

```
<xs:element name="Relationships">
  <xs:complexType mixed="true">
    <xs:sequence>
      <xs:element
        xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
        ref="rdf:RDF" minOccurs="1" maxOccurs="1"/>
    </xs:sequence>
  </xs:complexType>
</xs:element>
```

a

```
<rdf:RDF xmlns="mpeg21:correlationalontology"
  xmlns:mpeg21coreRelOnt="mpeg21:correlationalontology"
  .....>

  <owl:Ontology rdf:about="mpeg21:correlationalontology"/>

  <!-- Classes -->
  <owl:Class rdf:about="mpeg21:correlationalontology;DigitalItem"/>
  <owl:Class rdf:about="owl;Thing"/>

  <!-- Object Properties -->
  <owl:ObjectProperty rdf:about="&mpeg21coreRelOnt;interDIRelationship">
    <rdfs:domain rdf:resource="&mpeg21coreRelOnt;DigitalItem"/>
    <rdfs:range rdf:resource="&mpeg21coreRelOnt;DigitalItem"/>
  </owl:ObjectProperty>
</rdf:RDF>
```

b

```
<Descriptor>
  <Statement mimeType="text/xml">
    <dii:Relationships mimeType="application/rdf+xml">
      <rdf:RDF xmlns="individual:example:ontology#"
        xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#">
        <DigitalItem rdf:about="DI_A">
          <rdf:type rdf:resource="owl;DigitalItem"/>
          <correction rdf:resource="DI_B"/>
        </DigitalItem>
        <DigitalItem rdf:about="DI_B">
          <rdf:type rdf:resource="owl;DigitalItem"/>
        </DigitalItem>
      </rdf:RDF>
    </dii:Relationships>
  </Statement>
</Descriptor>
```

c

Fig. 2. MPEG-21 Extension Provisions

1  
2  
3  
4  
5  
6  
7 This element, whose schema definition is presented in Fig. 2.a, carries the relation-  
8 ship expressing information. It should be contained within a *did:Descriptor*. Each  
9 *did:Descriptor* binds to its parent *did:Item* element (which represents a DI), the rela-  
10 tionship expressing information.

11  
12 The *dii:Relationships* element carries an RDF/OWL metadata payload, describing  
13 the relationships in which the DI participates with other DIs. Relationships are ex-  
14 pressed as RDF *subject-predicate-object* triples. In each triple DIs may be either the  
15 subject or the object, and the predicate denotes the relationship between them.

16  
17 The MPEG-21 Core Ontology for DI Relationships (MPEG-21 CODIR), which is  
18 presented in Fig. 2.b, was also defined within the context of the work here presented.  
19 It was submitted to MPEG-21 together with the definition of the *dii:Relationships*  
20 element and thus, is now part of the same amendment to MPEG-21. It provides the  
21 concepts for both the *DigitalItem* and the base *interDIRelationship*.

22 The actual relationships, to be declared in the description of the relational context  
23 of digital resources, should be defined within custom, domain specific, ontologies.  
24 These ontologies are defined by adopting and extending the basic ontological model,  
25 provided by CODIR. As such, extended ontologies do not have to be defined or regis-  
26 tered with any central authority. Instead, they just have to be defined to address do-  
27 main specific needs and need only to be known within that domain. This independence  
28 avoids, for instance, the cumbersomeness involved when extending the pool of rela-  
29 tionship types of element *dii:RelatedIdentifier* (as mentioned earlier), which in fact  
30 requires the registration of the new type with a Registration Authority.

31  
32  
33 In agreement with the Linked-Data proposal, the solution here presented:

- 34  
35
  - uses RDF to express structured data and publish it on the Web;
  - uses RDF links to logically connect data from different data sources (interrelate  
36 different DIs);
  - identifies all resources by means of URIs.

37  
38  
39

40 The URIs employed for the identification of resources, are not necessarily HTTP  
41 ones, as in the Linked-Data proposal. Still, we believe that this is not an issue but  
42 actually, an improvement, as it renders this solution more location independent, and  
43 thus, more content-centric oriented.

44  
45 This solution is also perfectly compatible with MPEG-21 as it represents only the  
46 addition of an extra XML element, carrying XML expressed metadata (RDF/OWL),  
47 into an XML expressed standard (MPEG-21).

48  
49 An example of the mechanism's employment is the following: if *DI A* is a correc-  
50 tion to *DI B*, then, it may be said *DI A* is logically bound to *DI B* through the relation-  
51 ship of "*correction*". *DI A* is the subject, *DI B* the object and "*correction*" is the pred-  
52 icate of the relationship. Based on, and extending the MPEG-21 CODIR, a domain  
53 specific ontology can be defined (not presented in Fig. 2), containing the concept of  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3  
4  
5  
6  
7 correction relationship. Consequently, the explicit relationship between *DI A* and *DI B*  
8 may be expressed using the MPEG-21 standard, as presented in Fig. 2.c. The de-  
9 descriptor, presented in Fig. 2.c, would, typically, be located within the subject *DI*, i.e.  
10 *DI A*.

## 11 12 **5 Exploitation for Increased QoE**

13  
14 The relevance of the proposed mechanism, for providing increased QoE, may be  
15 demonstrated by analysing its use in different situations of multimedia resource con-  
16 sumption, among those that are flourishing on the Web. These scenarios can show the  
17 added value that can be obtained, in terms of objective and subjective user satisfac-  
18 tion.  
19

20  
21 In the next two sections we present two examples of multimedia resource consump-  
22 tion scenarios, where an innovative use is made of the developed mechanism. In them  
23 we highlight its relevance for an added QoE when searching, accessing and consuming  
24 multimedia content. Greater objective user satisfaction results from the mechanism's  
25 ability to assist the system in performing a more precise and automated resource dis-  
26 covery. This is a direct consequence of the mechanism' capability of enabling a flexi-  
27 ble, precise, and system-independent definition of logical relationships between digital  
28 objects. Greater subjective user satisfaction results from the increased flexibility,  
29 transparency and un-intrusiveness of the process. Users do not need to be aware of the  
30 existence of related content – the system automatically notifies them of varying types  
31 of resources with immediate interest to them. Accordingly, this leads to better meeting  
32 users' natural expectations and to enabling easier interaction with content.  
33

34  
35 Section 5.1 presents a simple exploitation example within the context of an e-  
36 Learning application, whereas section 5.2 presents a more complete exploitation ex-  
37 ample pertaining to the support of Weblogs (blogs).  
38

### 39 **5.1 e-Learning System**

40  
41 An advanced, distributed, Publish-Subscribe based, e-Learning platform is main-  
42 tained by a college to assist its students in their individual learning activities: “*Em-*  
43 *ploying that system Professor Watson publishes an InfoObject (IO) containing the*  
44 *material she lectures in each class, as a Lecture IO. Each such IO is made available*  
45 *for subscription to all students. Tom, a student who subscribed to the course, is auto-*  
46 *matically notified about the release of new lecture episodes. While watching the latest*  
47 *episode, he comes up with a doubt about a lectured subject. He produces a new Ques-*  
48 *tion IO with a question pertaining to the subject he has doubts about, and makes it*  
49 *public. The system then pushes the Question IO to all subscribed students. Mary,*  
50 *another student, knows the answer. She publishes it as a Response IO. Eventually*  
51 *Tom receives her answer”.*

1  
2  
3  
4  
5  
6  
7 e-Learning systems already exist that provide similar functionalities to those described above. However they typically depend on rigid and implicitly defined relationships, which are “hardcoded” into the system’s operational procedures. Expanding these solutions to deal with new situations is therefore complex, and often unfeasible without the realization of development work on them.

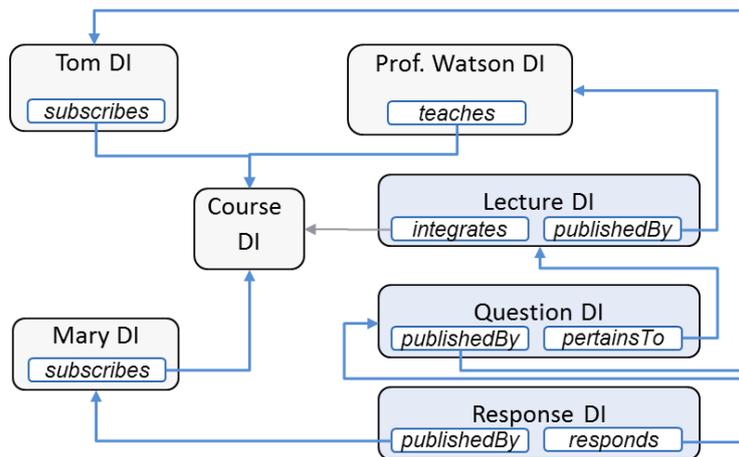

8  
9  
10  
11 The fact that, in the above presented solution, relational metadata is provided in an explicit way, enables even simple e-Learning systems, which do not resort to Artificial Intelligence (AI) mechanisms, to profit from this knowledge so as to provide a more dynamic and expandable set of services to users.

12  
13  
14  
15  
16  
17 For instance, in the above-described e-Learning scenario, one may identify that relationships-wise, Tom’s *Question IO* has a “*pertainsTo*” relationship, linking it to the *Lecture IO*; or that Mary’s *Response IO* has a “*responding*” relationship to Tom’s *Question IO*.

18  
19  
20  
21  
22 Employing MPEG-21, enriched with the mechanism that we have defined, this reality can easily be described and, thus, knowledge about it can also easily be preserved and shared. With this expanded tool it is possible to perform the declaration, packaging and inter-relating of all involved information assets and the identification and inter-relating of all involved real world entities (i.e. people, courses, etc.).

23  
24  
25  
26  
27 Specifically: all the relevant system entities (courses, students and teachers), are represented by an updateable DI, which identifies them and declares their relevant relationships (e.g. Tom’s DI declares that it maintains a “*subscription*” relationship with the course, which is represented by the *course DI*); all IOs are constituted as MPEG-21 DIs (within DID documents). Each such DI contains, besides its actual informational content, the specification of its relationships to the relevant other DIs. (e.g. the *Question IO DI* declares that it maintains a “*pertainsTo*” relationship with *Lecture IO DI*).

28  
29  
30  
31  
32  
33  
34  
35 The resulting scenario of DIs and their logical relationships is depicted in Fig. 3.

53  
54  
55

Fig. 3. Augmented e-Learning Relational Context

1  
2  
3  
4  
5  
6  
7 This way, the reliably and explicitly declared relational context described before,  
8 tells an e-Learning system, for instance, that: Tom and Mary are course students,  
9 whereas Dr. Watson is the course teacher; specific resources, wrapped up as DIs are  
10 the lectures that make up the course; other specific DIs are questions pertaining to the  
11 lectures whereas others are responses pertaining to those questions.

12 Knowledge of this information makes it easier for these systems to manipulate re-  
13 sources and interact with users. It grants them a higher flexibility as they may adapt to  
14 new situations by having their ontology updated, and may, therefore, more easily be  
15 expanded.

16  
17 Furthermore, more powerful systems that do resort to AI tools, may build on this  
18 information (which should, in principle, be error-free), to infer additional knowledge,  
19 establishing other types of relationships and thus offer users an enhanced service –  
20 they may, for instance, infer that *Question IOs* should be directed to the corresponding  
21 course teacher and that, if said teacher is replaced, they should be directed to the re-  
22 placing teacher.

23  
24 This simple, pertinent and semantically clear expression of relationships thus en-  
25 ables systems, as the one described above, to accurately and automatically detect inter-  
26 entity and inter-resource relationships and to operate on that knowledge, by means of  
27 programmed or intelligently derived directives, to infer subtle, semantic aspects of the  
28 reality in scope that would otherwise elude them. These systems are thus capable of a  
29 much more flexible adaptation to reality and to its changing demands and may, more  
30 easily, employ intelligent means to objectively increase the relevance and accuracy of  
31 the resources they bring to user attention. This enables them to diminish the effort  
32 required from users to find, or filter through irrelevant information until reaching,  
33 useful content, thus increasing subjective user QoE.

## 34 35 36 37 **5.2 Cloud Based Weblog Hosting**

### 38 **Introduction.**

39 Using the MPEG-21 specification, extended with our mechanism, it is possible to  
40 declare and package digital resources together with metadata defining their relational  
41 context. This information does not need to be extracted from the resources, nor stored  
42 and managed by a central repository. It is created, by resource producers, on a per DI  
43 basis and distributed alongside the resource/DI. This information is appropriate for  
44 distributed handling and thus, can be used to semantically empower cloud-based sys-  
45 tems such as a cloud-based weblog hosting service. The Blog-Cloud is a hypothetical  
46 system delivering such a service.

47  
48  
49 Blog-Cloud performs a completely distributed storage and management of re-  
50 sources. This is achieved in a location independent way (hence, content-centric orient-  
51 ed), taking advantage of the semantically precise declarations of inter resource rela-  
52 tionships (instead of http links). It can thus more efficiently and intelligently manage  
53 and distribute the resources that make up the weblogs.

### Weblog Data Structure.

The content of a Blog-Cloud weblog is divided through multiple DIDs of different types. The DIs, declared by these DIDs, carry different types of payloads and exhibit various types of relationships amongst themselves, as depicted in Fig. 4 and described below.

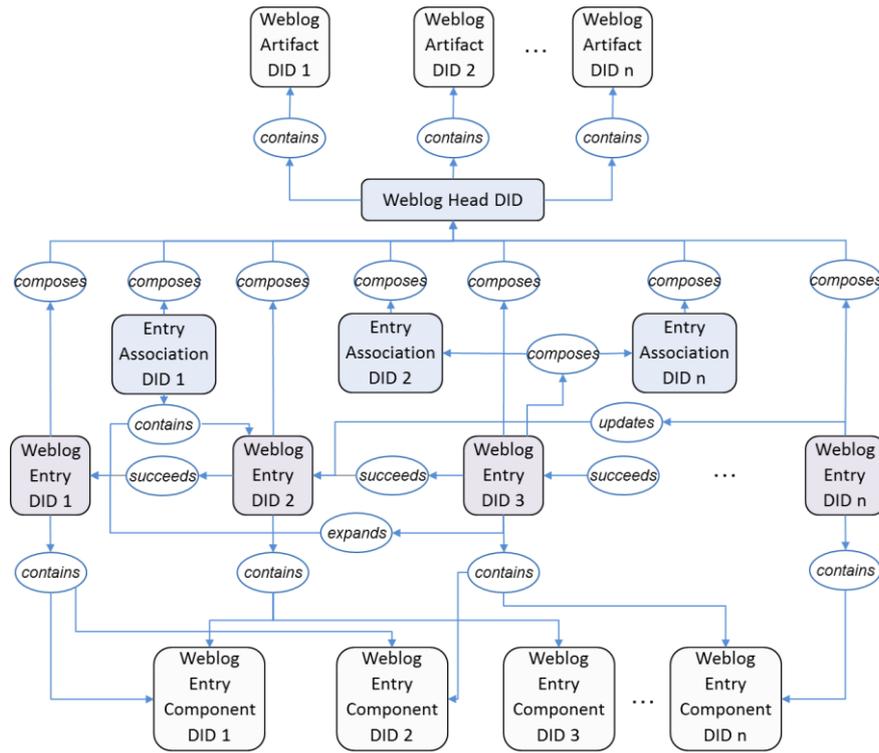

Fig. 4. Data Structure of a Blog-Cloud Weblog

The employed types of DIDs and the relationship declarations that they comprise are the following:

- *WH-DID*, the Weblog Head DID, which is the main DID. The *WH-DID* represents the whole blog and contains all the metadata (authors' identification, blog's main subjects, etc.) that pertains to the entire blog. It declares "containment" relationships to the Weblog Artefact DIDs (*WArt-DID*);
- *WArt-DID*, representing and containing a specific artefact (graphical, audio, audio-visual, etc.), employed in the graphical interface(s) of the weblog;
- *WE-DID*, the Weblog Entry DID, representing a single user (author) entry into the blog and contains only relevant metadata. It declares "containment" relationships towards the Weblog Entry Component DIDs (*WEC-DID*), which carry the actual text, image or video components of the entry. *WE-DIDs* also declare a "composition" relationship towards their corresponding *WH-DID* and may also declare a

1  
2  
3  
4  
5  
6  
7 number of other relationships towards each other. They may declare, for instance,  
8 that *WE-DID2 succeeds WE-DID1* or that *WE-DIDn updates WE-DID2*;

- 9 • *WEC-DID*, a Weblog Entry Content DID containing a single media component  
10 (text, image or video). It may be the target of “*containment*” relationships by many  
11 different *WE-DIDs*;
- 12 • *EA-DID*, the Entry Association DID, representing a specific association of blog  
13 entries. It may, for instance, represent the group of *WE-DIDs* which were added  
14 during a specific day, or that address a specific subject. When an *EA-DID* is creat-  
15 ed it will declare a “*containment*” relationship towards all the entries that are en-  
16 compassed by it and a “*composition*” relationship towards the *WH-DID*. Any *WE-*  
17 *DID* that logically belongs to it, which is added after the *EA-DID* has been pub-  
18 lished, will declare a “*composition*” relationship towards the latter.

19  
20 All of these DIDs will be independently distributed within Blog-Cloud and likewise  
21 independently retrieved by the client side, when necessary.

22 When addressing relationships, we freely refer to their targets as either DIDs or  
23 DIs. Even though they are not equal, given that each of the previously presented DIDs  
24 contains only a single DI, the two terms may be applied interchangeably.

### 25 26 27 **Weblog Ontology.**

28 The weblog ontology (depicted in Fig. 5) expands the CODIR ontology to define  
29 the concepts corresponding to the identified basic set of relationships between the  
30 weblog’s composing DIDs. It is defined on an exemplifying basis to demonstrate that  
31 there is a real interest in having a precise and explicit description of relationships be-  
32 tween resources in this field of application. It is not meant as a final word for an on-  
33 tology for said field.

### 34 35 36 **System Structure and Operation.**

37 The system is composed by a distributed set of server nodes that cooperatively  
38 serve client side requests.

39  
40 Within the universe of possible system DIDs, one may identify three different in-  
41 formation spaces:

- 42 • the space composed by the all the DIDs (more accurately, by their identifi-  
43 ers),  $S_{DID}$  ;
- 44 • the space composed by all the semantic relationships declared by all the system  
45 DIDs,  $S_{rel}$  ;
- 46 • the space composed by all the other semantic concepts declared in the semantic  
47 characterization metadata contained in the *WEC-DIDs* and *EA-DIDs*,  $S_{char}$  .

48  
49 Each of the server nodes is responsible for the storage and delivery of the infor-  
50 mation contained in a segment of each of the three spaces. The mapping of responsi-  
51  
52  
53

57  
58  
59  
60  
61  
62  
63  
64  
65

bility over these segments to specific individual servers is done in accordance with some algorithm known by all servers.

Each server node, ( $sn_i$ ), will thus be responsible for storing and delivering:

- a group of DIDs ( $S_{DID}^{sn_i}$ ), corresponding to a segment in  $S_{DID}$  ;
- a subset of inter-DI relationships information, ( $S_{rel}^{sn_i}$ ), corresponding to a segment in  $S_{rel}$  ;
- and a subset of DIs semantic characterization data, ( $S_{char}^{sn_i}$ ), corresponding to a segment in  $S_{char}$  .

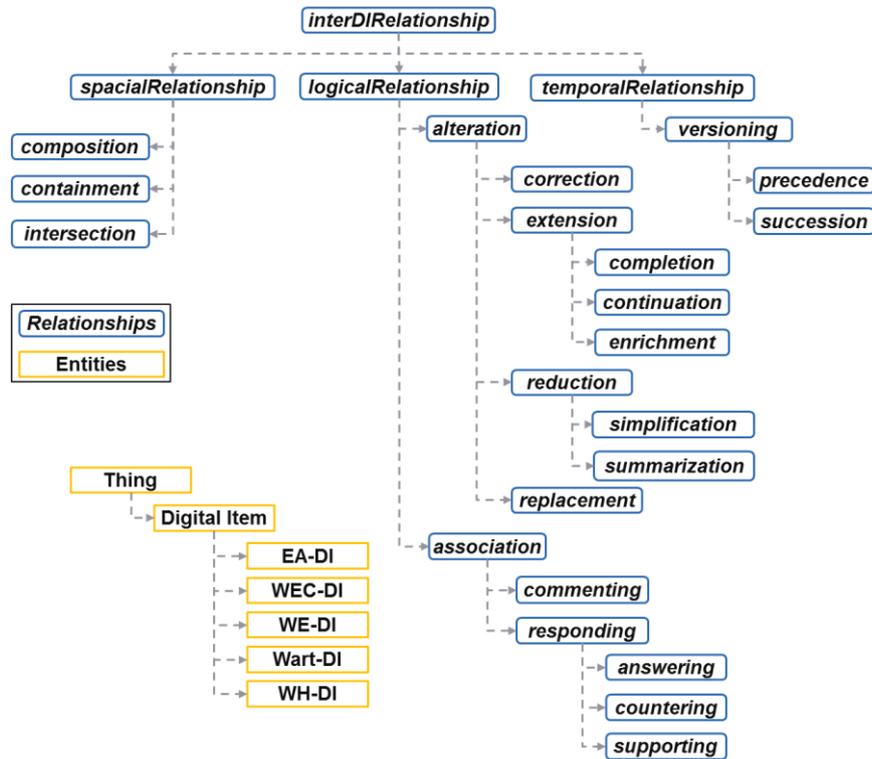

Fig. 5. Weblog Ontology

As all server nodes know the mapping algorithm. They, thus, know which server nodes to contact to obtain specific segments. Client nodes may not know that mapping. They will contact any known server node to obtain the desired information. If the latter is not the adequate one, it will redirect the client to the appropriate server.

Client nodes will interact with server nodes to request such operations as: DID searching (based on various specific criteria) or DID retrieval.

The subsections below present the system's main operations and capabilities, based on generic examples that highlight the possibilities offered by the employment of MPEG-21 DID and relationship declaration.

### Content Search.

A client node, (acting on behalf of a user), may perform different types of searches for DIs. The traditional search will be based on the DIs semantic characteristics. That is, searches operating on the  $S_{char}$  information space. However, the typical links between documents have been replaced and semantically enhanced by explicitly declared relationships using the extended MPEG-21 standard. Thus, there will also be searches operating on the  $S_{rel}^{n_i}$  information space.

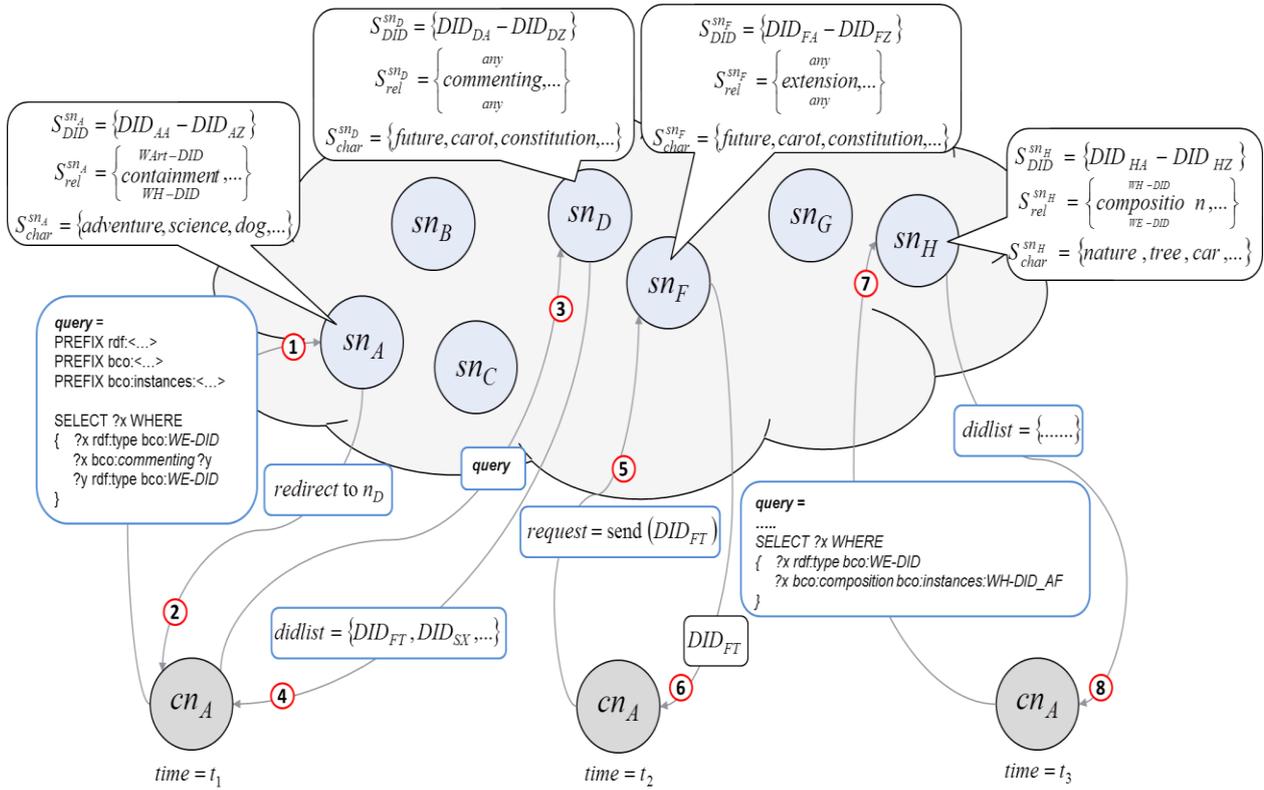

Fig. 6. Depiction of the System's Operation

Fig. 6 depicts a search operation of the latter type. In that figure, the top rounded rectangular callouts indicate the segments of the information spaces for which each

server node is responsible. For illustration purposes the  $S_{DID}$  space of system DIDs is defined as an interval of DID identifiers, where such identifiers are expressed as two-letters-long foot indexes (e.g.  $DID_{FA} - DID_{FZ}$ ). In this regard, server node  $sn_d$ , for instance, is responsible for the following segments of the system's information spaces:

- $S_{DID}^{sn_D} = \{DID_{DA} - DID_{DZ}\}$  – storing all DIDs contained in the set from  $DID_{DA}$  to  $DID_{DZ}$ ;
- $S_{rel}^{sn_D} = \left\{ \begin{array}{c} \text{any} \\ \text{commenting}, \dots \\ \text{any} \end{array} \right\}$  – storing the declaration of all *commenting* relationships between any two DIDs;

$S_{char}^{sn_D} = \{future, carot, constitution, \dots\}$  – storing the mapping of all attributes (keywords) in the set  $\{future, carot, constitution, \dots\}$ , to all the DIDs that they pertain to.

The bottom, rounded, rectangles indicate the content of exchanged messages. Some user, hosted at client node  $cn_A$ , issues a request for WE-DIs (blog entries), which are comments to other WE-DIs (regardless of any other aspect).  $cn_A$  compiles the adequate SPARQL query and sends it to one of its known server nodes,  $sn_A$  (arrow 1). However,  $S_{rel}^{sn_A}$  does not cover the targeted “commenting” relationship. It thus responds to  $cn_A$ , redirecting it to  $sn_D$  (arrow 2).  $cn_A$  re-sends the query to  $sn_D$  (arrow 3), which undertakes the searching procedure over its  $S_{rel}^{sn_D}$ , as the latter includes  $\begin{array}{c} \text{any} \\ \text{commenting} \\ \text{any} \end{array}$  (registry of all “commenting” relationships from any subject DI to any object DI). Information about all WE-DIs satisfying the search criteria, is compiled into a list ( $didlist = \{DID_{FT}, DID_{SX}, \dots\}$ ) and sent to  $cn_A$ . Finally,  $cn_A$  displays the obtained list to the user.

This procedure thus enables a new type of search to be performed over DIs, focusing on the relationships between on-line resources (such as the “commenting” relationships between blog entries exemplified above). These added search capabilities objectively enable a much more efficient and precise discovery and traversal of such logical connections. This makes it easier for users to navigate the mesh of posts and comments in a semantically precise manner, spending less time to find their desired information items, and, thus, contributing to a greater subjective user satisfaction and, hence, QoE.

1  
2  
3  
4  
5  
6  
7  
8  
9 *Search Optimization.*

10 Search engines operating on MPEG-21 DIDs, no longer have to “deduce” the types  
11 of logical connections binding digital resources, because these are formally specified.  
12 Smarter searches, i.e., searches with higher precision and recall (classic evaluation  
13 metrics of search techniques from the information retrieval science), may thus be  
14 achieved. Exploiting the semantic preciseness of ontologically defined inter-DI rela-  
15 tionships and the semantic proximity or distance between them easily attains this. This  
16 proximity is expressed by linking two inter-DI relationships (from the same or differ-  
17 ent ontologies), with the *rdf:subPropertyOf*, *owl:sameAs* or *skos:narrower* connec-  
18 tions. For instance the “*correction*” relationship may be an *rdf:subPropertyOf* the  
19 “*commenting*” relationship and the “*grammarcorrection*” relationship may be  
20 *skos:narrower* than the “*correction*” relationship.

21  
22 High precision is obtained by searching for DIs bound to other DIs by a specific  
23 semantic inter-DI relationship. High recall is obtained through the reasoning over  
24 inter-DI relationships that fall within a single ontology or which are interconnected  
25 over multiple ontologies.

26  
27 This way, to increase their precision, search queries for DIs that maintain a rela-  
28 tionship  $r_A$  with a target DI,  $DI_A$ , may be reformulated to search for DIs maintaining  
29 other inter-DI relationships with  $DI_A$ : these may be relationships from the same on-  
30 tology, in which case they will have an *rdf:subPropertyOf* connection with  $r_A$ ; or  
31 from different ontologies, in which case they will have an *skos:narrower* connection  
32 to  $r_A$ .  
33  
34  
35

```

59  
60  
61  
62  
63  
64  
65
```

Fig. 7 Depiction of Query Recall Increase Procedure

Searching for DIs related to  $DI_A$  through further inter-DI relationships, other than  $r_A$ , broadens its semantic target and may very well increase a search query's recall. Such additional relationships will be connected to the latter through *owl:sameAs* or *skos:broader*.

In light of the above, the SPARQL query sent by  $cn_A$  to the cloud (in arrows 1 and 3 of Fig. 6), may have its recall increased by broadening its target relationship from “commenting” to “responding”, in the manner depicted in Fig. 7

By enabling a higher searching precision and recall, this optimization mechanism evidently contributes to better satisfying user expectations regarding content discovery and, hence, increases user QoE.

#### Content Retrieval.

After a search has been performed, the user may choose to “consume” the WE-DID, identified as  $DID_{FT}$  (DID identified as FT). For this,  $cn_A$  will proceed to retrieve  $DID_{FT}$  from the cloud (as depicted in Fig. 6, arrow 5). If  $cn_A$  knows the identity of the server node responsible for delivery of the desired DID ( $sn_F$ ), it sends a request directly to it (the case depicted in Fig. 6). If not, it sends it to whatever server node it knows, and the latter will redirect it to the appropriate one.  $sn_D$  is the server node to contact, since  $S_{DID}^{sn_F} = \{DID_{FA} - DID_{FZ}\}$  and thus includes all DIDs from identifiers FA to FZ.

$sn_F$  will then deliver  $DID_{FT}$  to  $cn_A$ . The latter node will inspect the contents of  $DID_{FT}$  and discover the identity of its components *WEC-DIDs* (as  $DID_{FT}$  contains declarations of its relationships of “containment” towards said *WEC-DIDs*).  $cn_A$  will then proceed to retrieve all the *WEC-DIDs* (the actual media objects), that make up  $DID_{FT}$  (through the same procedure as the one just presented). It will then build the blog entry graphical presentation and expose it to the user.

Imagining that the user liked the selected blog entry, one can further suppose that she would like to retrieve the entire content of the blog. For that to occur,  $cn_A$  obtains the id of the entry's parent blog (*WH-DID*), from  $DID_{FT}$  (as it declares a “composition” relationship to it), which is, for instance,  $DID_{AF}$ . It then obtains from the cloud a list of all the *WE-DIDs* (entry DIDs), belonging to the blog. To do so,  $cn_A$  requests

1  
2  
3  
4  
5  
6  
7 from the server node ( $sn_H$ ) responsible for the segment of  $S_{rel}$  that con-  
8 tains  $composition^{WH-DID}$  (information about all the “composition” relationships from  $WE-$   
9  $DIDs$  towards  $WH-DIDs$ ), a list containing all of the  $WE-DID$  maintaining a “*compo-*  
10 *sition*” relationship towards  $DID_{AF}$  (arrows 7 and 8 of Fig. 6).  $cn_A$  may then proceed,  
11 as explained earlier in this section, to retrieve all the  $WEC-DIDs$  that each of the  $WE-$   
12  $DIDs$  contain.  
13  
14  
15

16 The described content retrieval procedure enables a flexible distribution of the con-  
17 tent delivery workload throughout the server nodes, and makes it easier for client  
18 nodes to locate and retrieve individual digital items. This, then, contributes to a speed-  
19 ier acquisition of the desired items, by users, and thus, to an increased user satisfaction  
20 and QoE.  
21

#### 22 *Content Browsing.*

23 Exploiting the inter-DI relationships the Weblog’s user interface could be designed  
24 to include links to relevant DIs, offering users a complete view of related resources  
25 and allowing them to explore content efficiently. Ontology-enhanced user interfaces  
26 [17], promote adaptability and personalization of the user interface according to user  
27 needs, and provide a highly interactive environment to browse through content, all of  
28 which fosters an increased user QoE. For instance, a Weblog user might select to view  
29 resources with a narrower or broader relationship to a blog post – e.g. DIs with “*re-*  
30 *sponding*” instead of the narrower “*commenting*” relationship.  
31  
32

#### 33 *Ranking.*

34 Inter-DI relationships can also be exploited to provide ranking among Weblog’s  
35 entries in a similar way to Google’s PageRank [18]. DIs with most incoming links will  
36 be promoted and users will benefit from the ranking functionality. Moreover, the ex-  
37 plicit declaration of the inter-DI relationship type eliminates the need to deduce the  
38 link type and can be exploited to enable sophisticated ranking methods, e.g. methods  
39 setting weights to the type of the relationship [19] or leveraging the relationship graph  
40 between the resources [20].  
41

42 Such more sophisticated ranking methods will provide better search results making  
43 it easier, and faster, for users to find relevant information resources, thus increasing  
44 their QoE.  
45

#### 46 **Final Remarks.**

47 Blog supporting systems are not new and already enable users to enter, search for and  
48 access content. However, such systems are typically maintained by highly centralized  
49 facilities, which enforce custom and rigid site and data structures and relationships  
50 (i.e. links). As such, the relationships between the delivered resources are “hardcoded”  
51 into these systems’ operational procedures, and the nature of such relationships is not  
52 precisely defined in terms of its meaning.  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3  
4  
5  
6  
7 This lack of semantically precise, explicitly expressed, inter-resource relationships  
8 means that there is little opportunity to enforce a more automated or “intelligent”  
9 mode of operation or evolution. Expanding such systems is thus a complex task as it  
10 implies “hardcoding” new relationships and relationship interpretations or processing  
11 procedures.

12  
13 The above sections demonstrate that the employment of relationally extended  
14 MPEG-21 innovatively enables digital resources and their metadata to be packaged  
15 into self-contained objects. It also enables the semantically precise definition of the  
16 relationships that bind such objects (in the mentioned metadata), webbing them into a  
17 coherent relational context.

18 These factors enable the definition of a distributed, server-side, architecture for  
19 supporting the WebLog system, which performs a dynamic sharing of the content  
20 distribution workload, as the responsibility over segments of the system’s information  
21 spaces may be dynamically adapted.

22 Furthermore, they permit the enforcing of a more versatile and intelligent interpreta-  
23 tion of the resource relationships and exploitation of the corresponding resources,  
24 enabling, for instance, smarter searches presenting higher precision and recall. All of  
25 this translates into an empowerment of users, in their ability to search, retrieve and  
26 access interesting content, and thus, into an increase in naturalness of interaction and  
27 quality of experience for the end user.  
28  
29  
30

## 31 **6 Contribution**

32  
33 The developed mechanism enables and stimulates the explicit and unambiguous decla-  
34 ration of the interior and exterior relational context of digital resources, clearly bind-  
35 ing that information to the resources. Interior relational context is the set of relation-  
36 ships that exist between the inner components of a Digital Item, whereas exterior rela-  
37 tional context is the set of relationships that exist between the DI itself and other DIs  
38 or other entities, (e.g. users). It does this in a manner that is aligned with emergent  
39 Semantic Web initiatives, notably the Linked-Data proposal, whilst being incorporated  
40 in a well-known open specification, the MPEG-21 standard, which natively provides  
41 extensive support for the digital representation and transaction of complex media re-  
42 sources.  
43  
44

45 It enables a semantically richer linking between digital resources. Unlike what hap-  
46 pens, for instance, with HTML (*<a>* and *<link>* tags) and the typical existing tagging  
47 solutions, the connections it establishes between resources are semantically precise,  
48 and their type is clearly defined and inscribed within a contextualizing ontology. Fur-  
49 thermore, as such connections are no longer static links between object locations (the  
50 typical http links), but are, instead, semantic bonds between universally identified  
51 digital objects, there is a decoupling of content and location. This enables a more  
52 dynamic resource placement, at the server side, and greater resource availability for  
53 the client side.  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3  
4  
5  
6  
7  
8 The total ontology pool (and, as such, the total pool of relationships) is unlimited –  
9 such ontologies are always extendible, bridgeable or may always be defined anew for  
10 any specific application case, if necessary. The mechanism in scope thus enables the  
11 development of an unlimited mesh of globally coherent ontologies, and the establish-  
12 ment of a global relational-semantic fabric involving all web resources in a self-  
13 contained way (within the resources themselves). This simplifies the emergence and  
14 operation of more complex systems and makes it easier to evolve and expand them.  
15

16 Given the semantically rich and coherent nature of this fabric, our mechanism, thus,  
17 enables the execution of novel and smarter searches, which profit from the interrela-  
18 tions between DIs and from the logical relationships between the interrelations them-  
19 selves (as they are defined within an ontological context). It enables, for instance, the  
20 exchange of query precision for recall and vice-versa, to be performed by automated  
21 provisions.  
22

23 The OAI-ORE standard provides some similar capabilities, as it also employs RDF  
24 for the description of inter-resource relationships. However, this standard mainly fo-  
25 cusses on the definition of digital resource aggregations. That is, it defines sets of  
26 digital resources as part of a specific body (the aggregation), specifying the relation-  
27 ships between resources, as internal relationships of that aggregation. Furthermore, the  
28 OAI-ORE standard does not seek to enable the self-containment of the concerned  
29 information objects, as it presupposes a separate distribution of the related resources  
30 and relating metadata.  
31

32  
33 The mechanism presented and exploited in this paper, is more versatile, as it oper-  
34 ates from a more flexible and universal perspective, whilst providing a more self-  
35 contained definition of the relational context of resources. In opposition to OAI-ORE,  
36 it does not require the definition of any aggregations nor is there any base granularity  
37 for an object to be able to describe inter-resource relationships. Every DI, defined in  
38 MPEG-21, may employ our mechanism to describe its relationships with the entire  
39 “digital world”. Given that the mechanism is part of the standard itself, those descrip-  
40 tions may, thus, be contained within the very DIs that they pertain to. Furthermore,  
41 whereas OAI-ORE is limited to the description of the interior relational context of an  
42 aggregation of resources, our extended MPEG-21 based tool is able to describe the  
43 entire, internal and external, relational context of any resource or DI, without any need  
44 to conceive or define it, as an aggregation of resources. So, if, for instance, one in-  
45 tends to declare that a DI is a “*comment*” to another DI, there is no need to define any  
46 artificial aggregation between the two resources. One simply defines the relationship  
47 and stores it in whatever DI it is relevant to store it.  
48

49  
50 For all of the above, it can be seen that the defined mechanism empowers MPEG-  
51 21 to become an optimal tool for the weaving of the relational tissue that permeates all  
52 digital resources. It enables the development of a complex, yet precise and easily in-  
53 terpretable relational fabric, which optimizes the handling, discovery and delivery of  
54  
55

6 digital resources, in a flexible and self-contained manner, by complex and distributed  
7 systems, as those presented in section 5. It, thus, makes it possible to provide users  
8 with a speedier, more precise and automated access to content of their immediate inter-  
9 est, which corresponds to an increase in their QoE, within the context of their inter-  
10 action with digital information resources on-line  
11

## 12 13 **7 Conclusions** 14

15  
16 The growing interpenetration of today's real and virtual worlds demands more coher-  
17 ent and universal ways of declaring resources as digital objects as well as more precise  
18 and semantically meaningful tools to specify the relationships between such resources.

19 Declaring resources as digital objects is exemplarily accomplished by MPEG-21, but  
20 a framework, and tools, for expressing and managing semantically rich relationships  
21 are presently missing.  
22

23 In this paper we have exposed MPEG-21's need for the addition of such relational  
24 capabilities. We then defined and described an extension, to MPEG-21, that enables it  
25 to declare, in an open, simple and efficient manner, semantically precise, inter-  
26 resources relationships.  
27

28 Furthermore, we went on to conceive two novel exploitation venues for the defined  
29 mechanism, with a special focus on an exemplifying a cloud-based content delivery  
30 system. We thus showed how different systems and services might use the extended  
31 MPEG-21 to optimize their operation, rendering it more semantically aware and "in-  
32 telligent" and enabling them to provide users with better experiences.

33 Our novel mechanism was scrutinized, approved and incorporated into ISO/IEC  
34 MPEG-21 standard, to provide it with the new, extended capabilities we have de-  
35 scribed.  
36

37 The approached exploitation venues, however, represent only a fraction of all that  
38 is possible. There is ample room for development regarding the exploitation of  
39 MPEG-21's relational capabilities. New forms of automatically exploiting the devel-  
40 oped tools, in different application areas can be conceived and experimented. Also,  
41 technologies and languages currently used for the relationships' declaration can be  
42 advanced or enriched.  
43  
44

## 45 **8 Acknowledgment** 46

47 The work here described was accomplished within the framework of the  
48 CONVERGENCE project [4]. The authors would like to thank all the  
49 CONVERGENCE partners for the fruitful collaboration, in particular those who have  
50 contributed to the development of the CONVERGENCE use cases. CEDEO and  
51 CNIT's work for this paper was also carried out within the framework of the  
52 FP7/NICT EU-JAPAN GreenICN ([www.greenicn.org](http://www.greenicn.org)) project.
