

Figure 1: Taxonomy of hybrid while-loops

We emphasise the distinction between our semantics and the more widespread *transition semantics* for hybrid automata [21]. Following Abramsky [1], the latter can be qualified as an *intensional semantics*, while we aim at an *extensional semantics*, meaning that e.g. we regard the two programs

$$x := 1 \text{ while true } \{\text{wait}(1)\} \quad \text{and} \quad x := 1 \text{ while true } \{\text{wait}(2)\}$$

as equivalent, while they would be distinct under the transition semantics. In a nutshell, by committing to the extensional view, we abstract away from specific choices of control states – a decision that could also be interpreted in hybrid automata setting and thus potentially lead to coarser, more flexible notions of automata equivalence.

One principal design decision we adopt in HYBCORE is to base it on the *fine-grain call-by-value* paradigm [27] – a refinement of Moggi’s computational λ -calculus, suitable for both operational and denotational semantics. Denotationally, we associate a hybrid computation with a *trajectory*, i.e. a map from a downward closed set D of non-negative real numbers (with $D = \emptyset$ for the *empty trajectory* representing non-progressive divergence). The supremum of D is called the *duration* of the hybrid computation. As shown in previous work [16, 17], such trajectories constitute a *hybrid monad* \mathbb{H} .

We introduce an operational semantics for HYBCORE and show that it is sound and (computationally) adequate w.r.t. \mathbb{H} . This result relies on a more lightweight operational semantics that keeps track of durations (i.e. execution times) only. We complement this latter semantics with a *duration monad* and prove analogous soundness and adequacy results for it.

Our results do not fit standard semantic frameworks for the following reasons:

- It is not possible to introduce iteration for the duration monad (as well as for the hybrid monad [16, 17]) via the usual least fixpoint argument, essentially due to the lack of canonical choice of divergence; the strategy we employ here, is thus to introduce a certain *coalgebraic* version of this monad equipped with a partial (guarded) Elgot iteration and then to suitably quotient it.

- Progressive divergence and Zeno behaviour, are principally *non-inductive* kinds of behaviour, which we manage to capture by allowing for infinitely many premises in the operational semantics rules.

- Our semantics for HYBCORE is essentially two-stage, and contains the aforementioned duration semantics as an auxiliary ingredient. The operational semantics rules thus feature two separate evaluation judgements.

Related work. In designing the different constructs of HYBCORE, we owe inspiration to Witsenhausen’s model of differential equations indexed by operations modes, a precursor of the concept of hybrid system [44], the *relational* Kleene algebra underlying *differential dynamic logic* [36] and also hybrid automata [21]. As already mentioned, we restrict ourselves to a purely hybrid setting, in particular we exclude non-determinism. This is not to say that we could not have considered non-determinism (in fact, there is also a non-deterministic hybrid monad [12]) but for the time being we focus on pure hybrid behaviour in isolation from other computational effects, such as non-determinism.

Suenaga and Hasuo [39] develop a somewhat similar while-language for hybrid systems but from a different semantic viewpoint: by unifying both continuous and discrete cyclic behaviour in a single while-construct that makes incrementations by infinitesimals. An interesting, principled approach to the semantics of *timed systems*, via an *evolution comonad*, is proposed by Kick, Power and Simpson [24]. The underlying functor of the evolution comonad is striking close to the functor underlying our hybrid monad, except that the former does not include empty trajectories and hence does not support non-progressive divergence.

As indicated above, in order to interpret hybrid while-loops, we necessarily went beyond standard semantic frameworks [38, 43], in particular because of the indispensable presence of various notions of divergence. This relates our work to the recent work on modelling productively non-terminating programs using a coalgebraic *delay monad* (previously called the *partiality monad*) [8, 13]. Indeed, our construction of the iteration operator on the *duration monad* in Section 5, is inspired by a technically similar procedure of quotienting the delay monad by weak bisimilarity [9], albeit in a different (constructive) setting.

2 PRELIMINARIES AND NOTATION

We will generally work in the category \mathbf{Set} of sets and functions, but also call on some standard idioms of category theory [5, 29]. By $|C|$ we refer to the objects of C , and by $\text{Hom}_C(A, B)$ (or $\text{Hom}(A, B)$, if no confusion arises) to the morphisms $f: A \rightarrow B$ from $A \in |C|$ to $B \in |C|$. We often omit indices at natural transformations. By \mathbb{N} , \mathbb{R} , \mathbb{R}_+ and $\bar{\mathbb{R}}_+$ we denote natural numbers (including 0), real numbers, non-negative real numbers and extended non-negative real numbers $\mathbb{R}_+ \cup \{\infty\}$ respectively. By $X + Y$ we denote a coproduct of X and Y , the corresponding coproduct injections $\text{inl}: X \rightarrow X + Y$ and $\text{inr}: Y \rightarrow X + Y$, and dually for products: $\text{fst}: X \times Y \rightarrow X$, $\text{snd}: X \times Y \rightarrow Y$. A category with finite products and coproducts is

distributive [10] if the natural transformation $[id \times inl, id \times inr]: X \times Y + X \times Z \rightarrow X \times (Y + Z)$ is an isomorphism, whose inverse we denote by $dist$. By $p \triangleleft b \triangleright q$ we abbreviate the if-then-else operator expanding as follows: $p \triangleleft \top \triangleright q = p$, $p \triangleleft \perp \triangleright q = q$. For time-dependent functions $e: \mathbb{R} \rightarrow Y$ we use the superscript notation e^t in parallel with $e(t)$ to emphasize orthogonality of the temporal dimension to the spatial one.

Following Moggi [31], we identify a *monad* \mathbb{T} on a category \mathbf{C} with the corresponding *Kleisli triple* $(T, \eta, (-)^*)$ consisting of an endomap T on $|\mathbf{C}|$, a $|\mathbf{C}|$ -indexed class of morphisms $\eta_X: X \rightarrow TX$, called the *unit* of \mathbb{T} , and the *Kleisli lifting* maps $(-)^*: \text{Hom}(X, TY) \rightarrow \text{Hom}(TX, TY)$ such that $\eta^* = id$, $f^* \eta = f$, $(f^* g)^* = f^* g^*$. Provided that \mathbf{C} has finite products, a monad \mathbb{T} on \mathbf{C} is *strong* if it is equipped with *strength*, i.e. a natural transformation $\tau_{X, Y}: X \times TY \rightarrow T(X \times Y)$ satisfying a number of standard coherence conditions (see e.g. [31]). Every monad \mathbb{T} on Set is strong [26] under $\tau_{X, Y} = \lambda(x, p). T(\lambda y. \langle x, y \rangle)(p)$. Morphisms of the form $f: X \rightarrow TY$ form the *Kleisli category* of \mathbb{T} , which has the same objects as \mathbf{C} , units $\eta_X: X \rightarrow TX$ as identities, and composition $(f, g) \mapsto f^* g$, also called *Kleisli composition*.

An (F) -*coalgebra* on $X \in |\mathbf{C}|$ for a functor $F: \mathbf{C} \rightarrow \mathbf{C}$ is a pair $(X, f: X \rightarrow FX)$. Coalgebras form a category whose morphisms $h: (X, f) \rightarrow (Y, g)$ satisfy $h \in \text{Hom}_{\mathbf{C}}(X, Y)$ and $(Fh)f = gh$. A final object $(\nu F, \text{out}: \nu F \rightarrow F\nu F)$ of this category is called a *final coalgebra* (see [42] for more details on coalgebras in semantics of (co)iteration).

3 A WHILE-LANGUAGE FOR HYBRID COMPUTATION

We start off by defining our core language for hybrid computation HYBCORE, following the *fine-grain call-by-value* paradigm [27]. First, we introduce types:

$$A, B, \dots ::= \mathbb{N} \mid \mathbb{R} \mid 1 \mid 2 \mid A \times B \quad (1)$$

and then postulate a signature Σ of typed operation symbols of the form $f: A \rightarrow B$ with $B \in \{\mathbb{N}, \mathbb{R}, 2\}$ for integer and real arithmetic, e.g. summation $+$: $\mathbb{N} \times \mathbb{N} \rightarrow \mathbb{N}$, and further primitives meant to capture time-dependent solutions of systems of ordinary differential equations: i.e. for every such system $\{\dot{x}_1 = f_1(\bar{x}, t), \dots, \dot{x}_n = f_n(\bar{x}, t)\}$ where \bar{x} is the vector $\langle x_1, \dots, x_n \rangle$ and $f_i: \mathbb{R}^n \times \mathbb{R} \rightarrow \mathbb{R}$, the signature Σ contains the symbol $int_{f_1, \dots, f_n}^i: \mathbb{R}^n \times \mathbb{R} \rightarrow \mathbb{R}$, representing the i -th projection of the corresponding unique (global) solution [35].

REMARK 1. *We do not study conditions ensuring existence of the solutions int_{f_1, \dots, f_n}^i , and instead work under the assumption that the functions f_i come from a sufficiently well-behaved class for which these solutions exist. Clearly, we could instead introduce a specific grammar of differential equations and make them part of the language. For example, we could use the following grammar for the $f_i(\bar{x}, t)$:*

$$f(\bar{x}, t), g(\bar{x}, t), \dots ::= \\ c \in \mathbb{R} \mid t \mid x \in \bar{x} \mid f(\bar{x}, t) + g(\bar{x}, t) \mid f(t) \cdot g(\bar{x}, t).$$

where $f(t)$ reads as $f(\bar{x}, t)$ with empty \bar{x} . This corresponds to systems of linear ordinary differential equations, which provide a sufficiently large stock of trajectories standardly used in hybrid system modelling [3]. A concrete choice of such grammar however would have no

bearing on our present results, but we expect to revisit this decision in future work devoted to reasoning and verification in HYBCORE.

Our language features two kinds of judgement,

$$\Gamma \vdash_v v: A \quad \text{and} \quad \Gamma \vdash_c p: A \quad (2)$$

for *values* and *computations*, respectively. These involve *variable contexts* Γ which are non-repetitive lists of *typed variables* $x: A$. We indicate the *empty context* as $-$ (dash), e.g. $- \vdash_c p: A$. The term language over these data is given in Figure 2. Programs of HYBCORE figure as terms p in computation judgements $\Gamma \vdash_c p: A$ and are inductively built over value judgements. Intuitively, the latter capture functions from Γ to A in the standard mathematical sense, and computation judgements capture functions from Γ to *trajectories* valued on A ; i.e. instead of single values from A , they return *functions* $D \rightarrow A$ valued on A with $D = [0, d]$ or $D = [0, d)$, e.g. $\emptyset = [0, 0)$ and $\mathbb{R}_+ = [0, \infty)$. Most of the constructs in Figure 2 are standard. Sequential composition (**seq**) for example reads as “bind the output of p to x and then feed it to q ”. The rule (**now**) converts a value v into an instantaneous computation, $[0, 0] \rightarrow A$, that returns v . The rules (**if**) and (**wh**) provide basic control structures (cf. [43]). Finally, (**tr**) converts a value into a computation by simultaneously abstracting over time and restricting the duration of the computation to the *union* of all those intervals $[0, d]$ on which v holds throughout. Note that the resulting interval can thus be either open or closed on the right. Intuitively, one can see (**tr**) as a ‘continuous’ while-loop since the trajectory captured by $t.v$ runs as long as the condition w is satisfied. For example, the computation judgement $\Gamma \vdash_c x := t.t \ \& \ t \leq 7: \mathbb{R}$ models the passage of time and runs whilst the latter does not surpass seven time units. This behaviour captures the essence of hybrid behaviour [44], which is now accommodated by hybrid automata and Platzer’s differential dynamic logic; our notation ‘&’ alludes precisely to this corresponding operator of the latter framework.

In contrast to fine-grain call-by-value [27], we have no conversions from computations to values, for we do not assume existence of higher order types, which potentially provide a possibility to *suspend* a program as a value and subsequently *execute* it, resulting in a computation. Adding these facilities to HYBCORE can be done standardly, but we refrain from it, as we intend our semantics to be eventually transferable from Set to more suitable universes, which need not be Cartesian closed, such as the category of topological spaces \mathbf{Top} .

Next we introduce some syntactic conventions for HYBCORE programs:

- We write $x := t.v \ \& \ r$ with $r \in \mathbb{R}$ for $\langle y, t \rangle := (x := t. \langle v, t \rangle \ \& \ \text{snd } x \leq r); [y]$ (assuming that the projection $\text{snd}: A \times B \rightarrow B$ and the predicate \leq are in Σ). Intuitively, this restricts the trajectory encoded by $t.v$ to the interval $[0, r]$.
- Sequential composition is right associative, that is, an iterated sequential composition in the form $x_1 := p_1; \dots; x_n := p_n; q$ should be parsed as $x_1 := p_1; (\dots; (x_n := p_n; q) \dots)$.
- We allow for programs of the form $x := p$ which abbreviate $x := p; [x]$.
- We omit the brackets $[-]$ if they can be easily reconstructed. E.g. $x := x + 1$ means $x := [x + 1]$ and thus $x := [x + 1]; [x]$, by the previous clause (e.g. this is used in Figure 1).

$$\begin{array}{l}
\text{(unit)} \quad \frac{}{\Gamma \vdash_v \star : 1} \qquad \text{(var)} \quad \frac{x : A \text{ in } \Gamma}{\Gamma \vdash_v x : A} \qquad \text{(sig)} \quad \frac{f : A \rightarrow B \in \Sigma \quad \Gamma \vdash_v v : A}{\Gamma \vdash_v f(v) : B} \\
\text{(true)} \quad \frac{}{\Gamma \vdash_v \text{true} : 2} \qquad \text{(false)} \quad \frac{}{\Gamma \vdash_v \text{false} : 2} \qquad \text{(prod)} \quad \frac{\Gamma \vdash_v v : A \quad \Gamma \vdash_v w : B}{\Gamma \vdash_v \langle v, w \rangle : A \times B} \\
\text{.....} \\
\text{(tr)} \quad \frac{\Gamma, t : \mathbb{R} \vdash_v v : A \quad \Gamma, x : A \vdash_v w : 2}{\Gamma \vdash_c x := t.v \ \& \ w : A} \qquad \text{(seq)} \quad \frac{\Gamma \vdash_c p : A \quad \Gamma, x : A \vdash_c q : B}{\Gamma \vdash_c x := p; q : B} \\
\text{(pm)} \quad \frac{\Gamma \vdash_v v : A \times B \quad \Gamma, x : A, y : B \vdash_c p : C}{\Gamma \vdash_c \langle x, y \rangle := v; p : C} \qquad \text{(now)} \quad \frac{\Gamma \vdash_v v : A}{\Gamma \vdash_c [v] : A} \\
\text{(if)} \quad \frac{\Gamma \vdash_v v : 2 \quad \Gamma \vdash_c p : A \quad \Gamma \vdash_c q : A}{\Gamma \vdash_c \text{if } v \text{ then } p \text{ else } q : A} \qquad \text{(wh)} \quad \frac{\Gamma \vdash_c p : A \quad \Gamma, x : A \vdash_v w : 2 \quad \Gamma, x : A \vdash_c q : A}{\Gamma \vdash_c x := p \ \text{while } w \ \{q\} : A}
\end{array}$$

Figure 2: HYBCORE's term formation rules for values (top) and computations (bottom)

Let us examine two examples of hybrid systems programmable in HYBCORE.

Example 3.1 (Bouncing ball). Consider the system of differential equations $\{\dot{u} = v, \dot{v} = g\}$ describing continuous movement of a ball in terms of its *height* u and *velocity* v with g being Earth's gravity. We postulate the corresponding solutions $\text{ball}_u : \mathbb{R}^2 \times \mathbb{R} \rightarrow \mathbb{R}$ and $\text{ball}_v : \mathbb{R}^2 \times \mathbb{R} \rightarrow \mathbb{R}$ in Σ so that $\text{ball}_u(x, y, t)$ and $\text{ball}_v(x, y, t)$ are the height and the velocity of the ball at time t , assuming x and y as the corresponding initial values (at time 0). Let ball be $\langle \text{ball}_u, \text{ball}_v \rangle$, and then e.g. $\langle u, v \rangle := t. \text{ball}(5, 0, t) \ \& \ u \geq 0$ encodes the behaviour of the ball starting from the moment when it is dropped from height 5 until it hits the ground. The HYBCORE program describing the resulting bouncing behaviour with infinitely many iterations is as follows:

```

⟨u, v⟩ := ⟨5, 0⟩
while true {
  ⟨u, v⟩ := t. ball(u, v, t) & u ≥ 0;
  ⟨u, v⟩ := ⟨u, -0.5v⟩
}

```

The movement thus programmed is depicted in Figure 3a. Note that the height is decreasing, tending to zero in the limit. This requires infinitely many iterations, but the process is finite in terms of physical time, because each iteration gets progressively shorter. This yields an example of Zeno behaviour [16, 23, 32], which is often dismissed in the hybrid systems literature, as justified by the fact that such behaviour is on the one hand not computationally realisable, and on the other hand notoriously difficult to analyse. Here, we commit ourselves to the task of faithful modelling Zeno behaviour as an inherent feature of physical, biological and other systems.

Example 3.2 (A simplistic cruise controller). The following program implements a simplistic cruise controller programmed in HYBCORE:

```

⟨u, v⟩ := ⟨0, 0⟩
while true {
  if v ≤ 120 then ⟨u, v⟩ := t. accel(u, v, t) & 3
  else ⟨u, v⟩ := t. brake(u, v, t) & 3
}

```

Here, $\text{accel} = \langle \text{accel}_u, \text{accel}_v \rangle$ and $\text{brake} = \langle \text{brake}_u, \text{brake}_v \rangle$ refer to the solutions of the systems of differential equations $\{\dot{u} = v, \dot{v} = 1\}$, $\{\dot{u} = v, \dot{v} = -1\}$ correspondingly. As the names suggest, accel is responsible for the acceleration, while brake is responsible for braking. Each iteration in the loop has the duration of three time units (due to the expression ' $\& 3$ '); at the beginning of each iteration the controller checks the current velocity, leading the vehicle to the target velocity of 120 km/h. This produces the oscillation pattern depicted in Figure 3b.

Example 3.3 (Signal sampling). The program below discretises a continuous-time signal $\text{signal} : \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R}$. The variable u , which is valued on natural numbers \mathbb{N} , represents the sampled signal, and the operation $\text{round} : \mathbb{R} \rightarrow \mathbb{N}$ rounds the input up to the closest natural number.

```

⟨u, v⟩ := ⟨0, 0⟩
while true {
  ⟨u, v⟩ := t. ⟨round(v), signal(v, t)⟩ & 1
}

```

The resulting computation when projected to the second Cartesian factor yields the original signal, while the same computation projected to the first Cartesian factor yields the corresponding discretised, or *sampled* signal. Here, we used the unit 1 as a *sampling interval*.

4 OPERATIONAL DURATION SEMANTICS

We now introduce an *operational duration semantics* of HYBCORE, both in small-step and big-step styles. In order to help build intuitions, we begin with the former. Duration semantics abstract away from the run-time behaviour of the program (i.e. its trajectory), and only provide the execution time and possibly the final result

Figure 3: Trajectories produced by hybrid programs

(i.e. the endpoint of the trajectory). The small-step judgements are defined on closed computation terms and have the form,

$$p \xrightarrow{d} q \quad \text{and} \quad p \xrightarrow{e} \quad (d \in \mathbb{R}_+, e \in \overline{\mathbb{R}}_+)$$

meaning that p one-step reduces to q in time d , or p one-step diverges in time e respectively, where only in the latter case the relevant time interval may be infinite. The derivation rules for these judgements are shown in Figure 4. These rules are essentially obtained by extending the standard call-by-value small-step semantics [43] by decorating the transitions with durations. The most distinctive rules are the ones addressing the abstraction construct (**tr**): intuitively, the resulting durations d are computed as the lengths of the largest interval $[0, t]$ on which the trajectory produced by v satisfies the predicate w throughout. The terminal value $\lfloor v[d/t] \rfloor$ is available precisely when the trajectory produced by v satisfies the predicate w at d . For example, for **line**: $\mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R}$ the global solution of the differential equation $\dot{x} = 1$, the program $x := t. \text{line}(0, t) \ \& \ x \leq 1$ one-step reduces to $\lfloor 1 \rfloor$ in time 1, and on the other hand, $x := t. \text{line}(0, t) \ \& \ x < 1$ one-step diverges in time 1.

Note a certain arbitrariness in defining *instantaneous transitions* $\xrightarrow{0}$. E.g. we could just as well use the following slightly more economical rule for reducing **if true then p else q** :

$$\frac{p \xrightarrow{d} p'}{\text{if true then } p \text{ else } q \xrightarrow{d} p'}$$

This would however not change the principal fact of pervasiveness of intermediate instantaneous transitions, as they are also triggered by unfolding while-loops, and cannot be completely eliminated from the corresponding rules.

We proceed to introduce the aforementioned big-step duration semantics. It associates a closed computation term p either with a pair d, v , consisting of a *duration* $d \in \mathbb{R}_+$ and a (closed) *terminal value* v , or with a (possibly infinite) duration $d \in \overline{\mathbb{R}}_+$. The latter case occurs e.g. if p exhibits Zeno behaviour or more generally if p is a while-loop that unfolds infinitely many times. The rules for big-step judgements are given in Figure 5.

Again, we focus only on the least standard rules. In both (**tr**₁^d) and (**tr**₂^d) the duration is identified with the length of the largest interval $[0, d]$ on which the condition w holds throughout, and subsequently each rule verifies if v is true at $t = d$. The rules (**seq**₁^d), (**seq**₂^d)

and (**seq**₃^d) capture the fact that durations of subsequent computations add up, unless the terminal value of the first computation is undefined, in which case the total duration of the program is the duration of the first subprogram. This behaviour is inherited inductively by while-loops via (**wh**₁^d)–(**wh**₄^d), and in addition we have a *non-inductive case* of infinitely many unfoldings of while-loops, as captured by the (infinitary) rule (**wh**₅^d). This allows for computing the duration of the program as the infinite sum $\sum_i d_i$.

REMARK 2. The rules (**wh**₃^d) and (**wh**₄^d) directly capture the inductive intuition in the semantics of while-loops, but notably these are the only rules which are not structural, in the sense that the programs in the premises are not structurally simpler than the corresponding programs in the conclusions. It is easy to see that (**wh**₃^d) and (**wh**₄^d) can be equivalently replaced by the families of structural rule schemes presented in Figure 6 in the style of (**wh**₅^d).

PROPOSITION 4.1 (DETERMINACY). The semantics in Figure 5 is deterministic, that is for every closed computation term p , there is (exclusively!) at most one judgement of the form $p \Downarrow d, v$ or $p \Downarrow d$ derivable using the rules of Figure 5.

PROOF. The proof runs routinely by induction over the number of computation constructs (bottom part of Figure 2) in p and by inspecting the rules in Figure 5, except for (**wh**₃^d) and (**wh**₄^d), which must be replaced by their structural analogues per Remark 2. \square

In order to relate small-step with big-step semantics, we define $p \xrightarrow{d} q$ and $p \xrightarrow{d}$ inductively by the following small-step judgements and closure rules:

$$\frac{}{[v] \xrightarrow{0} [v]} \quad \frac{p \xrightarrow{d} q}{p \xrightarrow{d} q} \quad \frac{p \xrightarrow{d} p' \quad p' \xrightarrow{e} q}{p \xrightarrow{d+e} q} \quad \frac{p \xrightarrow{d}}{p \xrightarrow{d}}$$

$$\frac{p \xrightarrow{d} p' \quad p' \xrightarrow{e}}{p \xrightarrow{d+e}} \quad \frac{p \xrightarrow{d_1} p' \quad p' \xrightarrow{d_2} p'' \quad \dots}{p \xrightarrow{d_1 + d_2 + \dots}}$$

The binary relation \xrightarrow{d} is then essentially the standard transitive closure, modulo the fact that durations are added along the way. The unary relation \xrightarrow{d} is derivable both from finite and infinite numbers of premises, e.g. in the Zeno behaviour case, as in Example 3.1.

Closed values, Closed computations:

$$v, w ::= x \mid \star \mid \text{true} \mid \text{false} \mid \langle v, w \rangle \mid f(v) \quad (f \in \Sigma)$$

$$p, q ::= \langle x, y \rangle := \langle v, w \rangle; p \mid \text{if } v \text{ then } p \text{ else } q \mid [v] \mid x := p; q \mid x := p \text{ while } v \{q\} \mid x := t.v \ \& \ w$$

Rules:

$$\begin{array}{c} \frac{}{\langle x, y \rangle := \langle v, w \rangle; q \xrightarrow{0} q[v/x, w/y]} \qquad \frac{p \xrightarrow{d} p'}{x := p; q \xrightarrow{d} x := p'; q} \qquad \frac{p \xrightarrow{d}}{x := p; q \xrightarrow{d} q} \\ \\ \frac{}{x := [v]; q \xrightarrow{0} q[v/x]} \qquad \frac{}{\text{if true then } p \text{ else } q \xrightarrow{0} p} \qquad \frac{}{\text{if false then } p \text{ else } q \xrightarrow{0} q} \\ \\ \frac{\forall s \leq d. w[v[s/t]/x] = \text{true} \quad \forall e > 0. \exists s \in (d, d + e). w[v[s/t]/x] = \text{false}}{x := t.v \ \& \ w \xrightarrow{d} [v[d/t]]} \qquad \frac{p \xrightarrow{d}}{x := p \text{ while } v \{q\} \xrightarrow{d} q} \\ \\ \frac{\forall s < d. w[v[s/t]/x] = \text{true} \quad w[v[d/t]/x] = \text{false}}{x := t.v \ \& \ w \xrightarrow{d} [v[d/t]]} \qquad \frac{w[v/x] = \text{false}}{x := [v] \text{ while } w \{q\} \xrightarrow{0} [v]} \\ \\ \frac{p \xrightarrow{d} p'}{x := p \text{ while } v \{q\} \xrightarrow{d} x := p' \text{ while } v \{q\}} \qquad \frac{w[v/x] = \text{true}}{x := [v] \text{ while } w \{q\} \xrightarrow{0} x := q[v/x] \text{ while } w \{q\}} \end{array}$$

Figure 4: Small-step duration operational semantics

THEOREM 4.2. For every closed computation term $p, p \xrightarrow{d} [v]$ iff $p \Downarrow d, v$ and $p \xrightarrow{d} [v]$ iff $p \Downarrow d$.

The claimed equivalence is entailed by the following Lemmas 4.3-4.7.

LEMMA 4.3. For any two closed programs p, q ,

- (1) unless $p \neq [v]$, the judgement $p \xrightarrow{d} q$ is derivable iff there exists a finite chain $p \xrightarrow{d_1} \dots \xrightarrow{d_n} q$ such that $\sum d_i = d$;
- (2) the judgement $p \xrightarrow{e} q$ is derivable iff
 - (a) either $p \xrightarrow{d_1} p' \dots \xrightarrow{d_n} q \xrightarrow{d_{n+1}}$ (with $n = 0$ meaning $p \xrightarrow{e} q$),
 - (b) or $p \xrightarrow{d_1} p' \xrightarrow{d_2} \dots$, with suitable p', \dots and q where $\sum_i d_i = d$.

Note that $[v]$ is not one-step reducible, and hence $[v] \xrightarrow{0} [v]$ is the only provable judgement of the form $[v] \xrightarrow{d} [v]$.

LEMMA 4.4. For every closed program $p, p \Downarrow d, v$ implies $p \xrightarrow{d} [v]$.

PROOF. We proceed by induction over the derivation of $p \Downarrow d, v$. Note that every rule in Figure 5, whose conclusion is of the form $p \Downarrow d, v$, has as premise big-step judgements only the judgements in the same form. In order to obtain a proof, we thus need to check the induction step for every rule. This is straightforward for all the rules, except for the ones for sequential composition and for while-loops. We consider the ones that apply, in detail.

(seq₃^d) The premises read as $p \Downarrow d, v$ and $q[v/x] \Downarrow e, w$, hence, by induction, $p \xrightarrow{d} [v], q[v/x] \xrightarrow{e} [w]$. If $p = [v]$ then $d = 0$ and $x := p; q \xrightarrow{0} q[v/x] \xrightarrow{e} [w]$, and hence $x := p; q \xrightarrow{d+e} [w]$, as desired. Otherwise, by Lemma 4.3,

$$x := p; q \xrightarrow{d_1} \dots \xrightarrow{d_n} x := [v]; q \xrightarrow{0} q[v/x] \xrightarrow{e} [w]$$

where $p \xrightarrow{d_1} \dots \xrightarrow{d_n} [v], d = \sum_i d_i$. Hence, again $x := p; q \xrightarrow{d+e} [w]$. (wh₂^d) The premises imply by induction hypothesis $p \xrightarrow{d} [w]$. The case $p = [w]$ is as in the previous clause. Otherwise, we have

$$x := p \text{ while } v \{q\} \xrightarrow{d_1} \dots \xrightarrow{d_n} x := [w] \text{ while } v \{q\} \xrightarrow{0} [w]$$

with $p \xrightarrow{d_1} \dots \xrightarrow{d_n} [w], d = \sum_i d_i$, which yields the derivation $x := p \text{ while } v \{q\} \xrightarrow{d} [w]$.

(wh₄^d) We obtain $p \xrightarrow{d} [w]$ and $x := q[w/x] \text{ while } v \{q\} \xrightarrow{r} [u]$ from the rule premises. After disregarding the obvious case $p = [w]$, we obtain similarly to the previous clause

$$x := p \text{ while } v \{q\} \xrightarrow{d_1} \dots \xrightarrow{d_n} x := [w] \text{ while } v \{q\} \xrightarrow{r} [u]$$

Hence $x := p \text{ while } v \{q\} \xrightarrow{d+r} [u]$, and we are done. \square

LEMMA 4.5. For every closed program $p, p \xrightarrow{d} [v]$ implies $p \Downarrow d, v$.

PROOF. It suffices to show that $p \xrightarrow{d} p'$ with $p' \Downarrow r, v$ imply $p \Downarrow d+r, v$, from which the claim follows by obvious induction. The latter statement in turn follows by induction over the derivation of $p \xrightarrow{d} p'$ using the rules in Figure 4. \square

We consider the proofs of the analogous results in the non-terminating cases in more detail.

LEMMA 4.6. For every closed program $p, p \Downarrow d$ implies $p \xrightarrow{d} .$

PROOF. The proof runs analogously to the proof of Lemma 4.4 and occasionally calls the latter. Again, we restrict ourselves to

$$\begin{array}{c}
\frac{}{\llbracket \Gamma \vdash_v \star : 1 \rrbracket = \lambda \bar{x}. \star} \qquad \frac{}{\llbracket \Gamma \vdash_v x_i : A \rrbracket = \lambda \bar{x}. x_i} \qquad \frac{\llbracket \Gamma \vdash_v v : A \rrbracket = h \quad f : A \rightarrow B \in \Sigma}{\llbracket \Gamma \vdash_v f(v) : B \rrbracket = f h} \\
\frac{}{\llbracket \Gamma \vdash_v \text{true} : 2 \rrbracket = \lambda \bar{x}. \text{true}} \qquad \frac{}{\llbracket \Gamma \vdash_v \text{false} : 2 \rrbracket = \lambda \bar{x}. \text{false}} \qquad \frac{\llbracket \Gamma \vdash_v v : A \rrbracket = h \quad \llbracket \Gamma \vdash_v w : B \rrbracket = l}{\llbracket \Gamma \vdash_v \langle v, w \rangle : A \times B \rrbracket = \langle h, l \rangle} \\
\cdots \\
\frac{\llbracket \Gamma \vdash_v v : A \times B \rrbracket = h \quad \llbracket \Gamma, x : A, y : B \vdash_c p : C \rrbracket = l}{\llbracket \Gamma \vdash_c \langle x, y \rangle := v : p : C \rrbracket = l \langle \text{id}, h \rangle} \qquad \frac{\llbracket \Gamma \vdash_c p : A \rrbracket = h \quad \llbracket \Gamma, x : A \vdash_c q : B \rrbracket = l}{\llbracket \Gamma \vdash_c x := p : q : B \rrbracket = l \star \tau \langle \text{id}, h \rangle} \\

\frac{\llbracket \Gamma, t : \mathbb{R} \vdash_v v : A \rrbracket = h \quad \llbracket \Gamma, x : A \vdash_v w : 2 \rrbracket = b \quad \lambda \bar{x}. \sup\{e \mid \forall t \in [0, e]. b(\bar{x}, h(\bar{x}, t))\} = d}{\llbracket \Gamma \vdash_c x := t. v \ \& \ w : A \rrbracket = \lambda \bar{x}. \langle d(\bar{x}), h(\bar{x}, d(\bar{x})) \rangle \triangleleft b(\bar{x}, h(\bar{x}, d(\bar{x}))) \triangleright d(\bar{x})} \\
\frac{\llbracket \Gamma \vdash_c p : A \rrbracket = h \quad \llbracket \Gamma, x : A \vdash_v v : 2 \rrbracket = b \quad \llbracket \Gamma, x : A \vdash_c q : A \rrbracket = l}{\llbracket \Gamma \vdash_c x := p \ \text{while} \ v \ \{q\} : A \rrbracket = \lambda \bar{x}. ((\lambda x. (Q \text{inr}) l(\bar{x}, x) \triangleleft b(\bar{x}, x) \triangleright \eta \text{inl } x)^\dagger)^\star(h(\bar{x}))}
\end{array}$$

Figure 7: Denotational duration semantics

postulated in (\mathbf{wh}_5^d) , the latter implying that even *divergent* computations produce meaningful durations. We thus proceed to make \mathbb{Q} into an *Elgot monad* in a different way. To that end we will first introduce a fine-grained version of \mathbb{Q} , roughly mimicking the small-step duration semantics.

Definition 5.4 (Layered duration monad, Guardedness). Let $\hat{Q}X = \nu \gamma. (X + \mathbb{R}_+ \times \gamma)$, which extends to a monad \hat{Q} by general results [41]. On **Set** this monad takes a concrete particularly simple form: $\hat{Q}X = \mathbb{R}_+^\star \times X \cup \mathbb{R}_+^\omega$, $\eta(x) = \langle \epsilon, x \rangle \in \hat{Q}X$, and

$$(f : X \rightarrow \hat{Q}Y)^\star(w, x) = \langle wu, y \rangle \quad \text{if } f(x) = \langle u, y \rangle \in \mathbb{R}_+^\star \times Y,$$

$$(f : X \rightarrow \hat{Q}Y)^\star(w, x) = wu \quad \text{if } f(x) = u \in \mathbb{R}_+^\omega,$$

$$(f : X \rightarrow \hat{Q}Y)^\star(w) = w.$$

A morphism $f : X \rightarrow \hat{Q}(Y + Z)$ is called *guarded* when for every $x \in X$ if $f(x) = (w, \text{inr } z)$ then the word w is non-empty. Guardedness of $f : X \rightarrow \hat{Q}(Y + X)$ intuitively means that the iteration operator applied to f successively produces durations as the loop unfolds, in other words that the loop is *progressive*. This provides a fine-grained semantics of divergence, for every infinite stream of durations thus obtained contributes as a specific divergent behaviour.

PROPOSITION 5.5. *For a guarded morphism $f : X \rightarrow \hat{Q}(Y + X)$, there is a unique $f^\dagger : X \rightarrow \hat{Q}Y$, satisfying the fixpoint equation $f^\dagger = [\eta, f^\dagger]^\star f$.*

PROOF. In the coalgebraic form, this was shown in previous work for a large class of monads [30, 40] including \hat{Q} . \square

We now render \mathbb{Q} as a quotient of \hat{Q} and derive a (total) Elgot iteration operator on \mathbb{Q} from the partial one on \hat{Q} , as follows. Note that every QX is a quotient of $\hat{Q}X$ under the “weak bisimulation” relation \approx generated by the clauses,

$$\langle r_1 \dots r_n, x \rangle \approx \langle s_1 \dots s_m, x \rangle \quad (r_1 + \dots + r_n = s_1 + \dots + s_m)$$

$$r_1 r_2 \dots \approx s_1 s_2 \dots \quad \left(\sum_i r_i = \sum_j s_j \right)$$

Then let $\rho_X : \hat{Q}X \rightarrow QX$ be the emerging quotienting map:

$$\rho_X(r_1 \dots r_n, x) = \langle \sum_i r_i, x \rangle, \quad \rho_X(r_1 r_2 \dots) = \sum_i r_i,$$

and let $v_X : QX \rightarrow \hat{Q}X$ be defined in the following way:

$$v_X(d, x) = \langle d, x \rangle, \quad v_X(r \in QX \cap \mathbb{R}_+) = r 0^\omega, \quad v_X(\infty) = 1^\omega.$$

Note that by definition, for any $f : X \rightarrow Q(Y + X)$, $v f : X \rightarrow \hat{Q}(Y + X)$ is guarded.

THEOREM 5.6. *The following is true for ρ_X and v_X :*

- (1) every ρ_X is a left inverse of the corresponding v_X ;
- (2) ρ is a monad morphism;
- (3) for any guarded $f : X \rightarrow \hat{Q}(Y + X)$, $\rho f^\dagger = \rho(v \rho f)^\dagger$.

PROOF. (1) is easy to see by definition, and (2) is essentially due to the fact that countable summation of non-negative real numbers is associative. Let us check (3). For every $x_0 \in X$, there are three possibilities:

- (a) there is a finite sequence of elements x_0, \dots, x_n in X such that $f(x_i) = \langle w_i, x_{i+1} \rangle$ for $i < n$, $f(x_n) = \langle w_n, y \rangle \in \mathbb{R}_+^\star \times Y$ and $f^\dagger(x_0) = \langle w_0 \dots w_n, y \rangle$;
- (b) there is a finite sequence of elements x_0, \dots, x_n in X such that $f(x_i) = \langle w_i, x_{i+1} \rangle$ for $i < n$, $f(x_n) = w_n \in \mathbb{R}_+^\omega$ and $f^\dagger(x_0) = w_0 \dots w_n$;
- (c) there is an infinite sequence of elements x_0, \dots in X such that $f(x_i) = \langle w_i, x_{i+1} \rangle \in \mathbb{R}_+^\star \times X$ for $i \in \omega$ and $f^\dagger(x_0) = w_0 w_1 \dots$.

These three cases fully describe how the iteration operator of \hat{Q} works. In each case, it is easy to check the identity in question: e.g. in (a) $\rho f^\dagger(x_0) = \rho \langle w_0 \dots w_n, y \rangle = \langle \sum w_0 + \dots + \sum w_n, y \rangle$ and then $\rho(v \rho f)^\dagger(x_0) = \rho \langle \sum w_0 \dots \sum w_n, y \rangle = \langle \sum w_0 + \dots + \sum w_n, y \rangle$ where by $\sum w_i$ we mean the sum of elements of the vector $w_i \in \mathbb{R}_+^\star$. The remaining cases (b) and (c) are handled analogously. \square

We immediately obtain the following corollary of Theorem 5.6.

COROLLARY 5.7. \mathbb{Q} is an Elgot monad with the Elgot iteration sending $f: X \rightarrow Q(Y + X)$ to $\rho(vf)^\dagger: X \rightarrow QY$.

PROOF. In the terminology of [20], Theorem 5.6 implies that the pair (ρ, v) is an *iteration-congruent retraction*. Thus, by [20, Theorem 21], \mathbb{Q} is indeed an Elgot monad under the iteration operator described above. \square

Note that the Elgot iteration of \mathbb{Q} adds the durations produced by a map $f: X \rightarrow Q(Y + X)$ along the respective iteration process, the latter realised by feeding back to f values of type X it produces. For example, if $f(x) = \langle 1, \text{inr } x \rangle$ then $\rho(vf)^\dagger(x) = 1 + 1 + \dots = \infty$; if $f(n + 1) = \langle 1/2, \text{inr } n \rangle$ and $f(0) = \langle 0, \text{inl } \star \rangle$ then $\rho(vf)^\dagger(n) = \langle n * (1/2), \star \rangle$.

Using Elgot iteration provided by Corollary 5.7, we can now define a denotational semantics of **HYB**CORE in the following way. We identify the types in (1) with what they denote in **Set**, i.e. natural numbers, real numbers, the one element set $\{\star\}$, the two-element set $\{\top, \perp\}$ and Cartesian products respectively. For a variable context $\Gamma = (x_1: A_1, \dots, x_n: A_n)$, let $\llbracket \Gamma \rrbracket = A_1 \times \dots \times A_n$ (specifically, $\llbracket \Gamma \rrbracket = 1$ if Γ is empty). We will use \bar{x} to refer to the tuples $\langle x_1, \dots, x_n \rangle$ where $\Gamma = (x_1: A_1, \dots, x_n: A_n)$. The semantics $\llbracket \Gamma \vdash_v v: A \rrbracket$ and $\llbracket \Gamma \vdash_c p: A \rrbracket$ are respectively maps of type $\llbracket \Gamma \rrbracket \rightarrow A$ and $\llbracket \Gamma \rrbracket \rightarrow QA$, inductively defined in Figure 7.

THEOREM 5.8 (SOUNDNESS AND ADEQUACY). *Given a computation judgement $\vdash_c p: A$,*

$$\begin{aligned} p \Downarrow d & \quad \text{iff} \quad \llbracket \vdash_c p: A \rrbracket = d, \\ p \Downarrow d, v & \quad \text{iff} \quad \llbracket \vdash_c p: A \rrbracket = \langle d, \llbracket \vdash_v v: A \rrbracket \rangle. \end{aligned}$$

PROOF. First we establish *soundness*, which means simultaneously that $p \Downarrow d$ implies $\llbracket \vdash_c p: A \rrbracket = d$ and $p \Downarrow d, v$ implies $\llbracket \vdash_c p: A \rrbracket = \langle d, \llbracket \vdash_v v: A \rrbracket \rangle$. By induction over the derivation length in the proof system of Figure 5 this amounts to checking that every rule preserves these implications. This is done routinely for most of the rules. Consider some instances.

(tr₁^d) The assumption reads as $x := t.v \ \& \ w \Downarrow d, v[d/t]$. The premises of the rule imply

$$\begin{aligned} d & \geq \sup\{e \mid \forall s \in [0, e]. w[v[s/t]/x] = \text{true}\}, \\ d & \leq \sup\{e \mid \forall s \in [0, e]. w[v[s/t]/x] = \text{true}\}, \end{aligned}$$

hence $d = \sup\{e \mid \forall s \in [0, e]. w[v[s/t]/x] = \text{true}\}$. Assuming $\llbracket t: \mathbb{R} \vdash_v v: A \rrbracket = h$ and $\llbracket x: A \vdash_v w: 2 \rrbracket = b$, the latter can be rewritten as

$$d = \sup\{e \mid \forall t \in [0, e]. b(h(t))\}.$$

The left premise of **(tr₁^d)** also implies that $b(h(d)) = \text{true}$, and hence the corresponding rule in Figure 7 produces $\llbracket \vdash_c x := t.v \ \& \ w: A \rrbracket = \langle d, h(d) \rangle$ as required.

(tr₂^d) The assumption reads as $x := t.v \ \& \ w \Downarrow d$. Assuming $\llbracket \vdash_v t: \mathbb{R} \vdash_v v: A \rrbracket = h$ and $\llbracket \vdash_v x: A \vdash_v w: 2 \rrbracket = b$, like in the previous clause, the premises of the rule imply $d = \sup\{e \mid \forall t \in [0, e]. b(h(t))\}$, however, now $b(h(d)) = \text{false}$. By using the same rule from Figure 7, we obtain $\llbracket \vdash_c x := t.v \ \& \ w: A \rrbracket = d$.

(wh₄^d) Suppose that $x := p \ \text{while} \ v \ \{q\} \Downarrow d + r, u$ is obtained from the respective premises of **(wh₄^d)** and $\llbracket \vdash_c p: A \rrbracket = h$, $\llbracket x: A \vdash_v v: 2 \rrbracket = b$, $\llbracket x: A \vdash_c q: A \rrbracket = l$. We obtain that $h =$

$\langle d, w \rangle$ for some w (by induction), $b(w) = \text{true}$ and $\llbracket \vdash_c x := q[w/x] \ \text{while} \ v \ \{q\}: A \rrbracket = \langle r, \llbracket \vdash_v u: A \rrbracket \rangle$ (by induction). Let

$$f = \lambda x. (Q \ \text{inr})(l(x)) \triangleleft b(x) \triangleright \eta(\text{inl } x)$$

and note that $\langle r, \llbracket \vdash_v u: A \rrbracket \rangle = (f^\dagger)^\star(l(w))$, which means that $l(w) = \langle e, c \rangle$, $f^\dagger(c) = \langle e', \llbracket \vdash_v u: A \rrbracket \rangle$ and $e + e' = r$ for suitable e, e' and c . Therefore, using the fixpoint identity for $(-)^\dagger$, $\llbracket \vdash_c x := p \ \text{while} \ v \ \{q\}: A \rrbracket = (f^\dagger)^\star(h) = (f^\dagger)^\star(d, w) = [\eta, f^\dagger]^\star f^\star(d, w) = (f^\dagger)^\star(d + e, c) = \langle d + e + e', \llbracket \vdash_v u: A \rrbracket \rangle = \langle d + r, \llbracket \vdash_v u: A \rrbracket \rangle$ and we are done.

(wh₅^d) Suppose that $x := p \ \text{while} \ v \ \{q\} \Downarrow \sum_i d_i$ is obtained from the premises $p \Downarrow d_0, w_0, q[w_i/x] \Downarrow d_{i+1}, w_{i+1}$ ($i \in \omega$), and $v[w_i/x] = \text{true}$ ($i \in \omega$) by **(wh₅^d)**. By induction, $\llbracket \vdash_c p: A \rrbracket = \langle d_0, \llbracket \vdash_v w_0: A \rrbracket \rangle$, and for every $i \in \omega$, $\llbracket \vdash_c q[w_i/x]: A \rrbracket = l(\llbracket \vdash_v w_i: A \rrbracket) = \langle d_{i+1}, \llbracket \vdash_v w_{i+1}: A \rrbracket \rangle$ where $l = \llbracket x: A \vdash_c q: A \rrbracket$. Note also that $b(\llbracket \vdash_v w_i: A \rrbracket) = \text{true}$ for every $i \in \omega$ with $b = \llbracket x: A \vdash_v v: 2 \rrbracket$. Let again

$$f = \lambda x. (Q \ \text{inr})(l(x)) \triangleleft b(x) \triangleright \eta(\text{inl } x)$$

and observe that $f(\llbracket \vdash_v w_i: A \rrbracket) = (Q \ \text{inr})(l(\llbracket \vdash_v w_i: A \rrbracket)) = \langle d_{i+1}, \text{inr}(\llbracket \vdash_v w_{i+1}: A \rrbracket) \rangle$. Now, by definition of $(-)^\dagger$ of \mathbb{Q} , $(vf)^\dagger(\llbracket \vdash_v w_0: A \rrbracket) = d_1 d_2 \dots$, and therefore in \mathbb{Q} , $f^\dagger(\llbracket \vdash_v w_0: A \rrbracket) = \rho(vf)^\dagger(\llbracket \vdash_v w_0: A \rrbracket) = \sum_{i>0} d_i$. Therefore, $\llbracket \vdash_c x := p \ \text{while} \ v \ \{q\}: A \rrbracket = (f^\dagger)^\star(d_0, \llbracket \vdash_v w_0: A \rrbracket) = d_0 + f^\dagger(\llbracket \vdash_v w_0: A \rrbracket) = \sum_i d_i$, as desired.

The remaining adequacy direction reads as follows: $\llbracket \vdash_c p: A \rrbracket = d$ implies $p \Downarrow d$ and $\llbracket \vdash_c p: A \rrbracket = \langle d, \llbracket \vdash_v v: A \rrbracket \rangle$ implies $p \Downarrow d, v$. In order to obtain it by induction over derivations in Figure 7, we slightly strengthen the induction invariant as follows: for every substitution σ sending variables from Γ to values of corresponding types, $\llbracket \Gamma \vdash_c p: A \rrbracket = d$ implies $p\sigma \Downarrow d\sigma$ and $\llbracket \Gamma \vdash_c p: A \rrbracket = \langle d, \llbracket \Gamma \vdash_v v: A \rrbracket \rangle$ implies $p\sigma \Downarrow d\sigma, v\sigma$. It is then verified routinely that every rule in Figure 7 preserves this invariant. \square

6 EVOLUTION SEMANTICS

Building on the duration semantics of the previous section, we will now present a big-step *evolution operational semantics* for hybrid programs, which incorporates the former as a critical ingredient. In particular, both semantics will be needed for providing the aforementioned adequacy result. The new semantics relates a closed computation term p with its *trajectory*, i.e. the range of time-indexed values produced by the execution of p – recall for instance the bouncing ball and cruise controller described in Section 3. More specifically, the corresponding big-step relation \Downarrow connects a closed computation term p and a time instant t with the value v to which p evaluates at t , in symbols $p, t \Downarrow v$. The corresponding derivation rules are presented in Figure 8. These rules recur to the duration semantic judgements governed by the rules in Figure 5. Unlike duration semantics, evolution semantics is not total: for example, for a given computation p , $p, t \Downarrow v$ may not be derivable for any v and t , which yields an *empty trajectory* for p , denotationally a totally undefined function $\emptyset \rightarrow A$.

Let us discuss the non-obvious rules of this semantics, starting with **(seq₁^o)** which takes infinite families of judgements as premises.

$$\begin{array}{c}
(\mathbf{seq}_1^e) \frac{(p, s \Downarrow v_s)_{s \leq t} \quad (q[v_s/x], 0 \Downarrow w_s)_{s \leq t}}{x := p; q, t \Downarrow w_t} \quad (\mathbf{seq}_2^e) \frac{p \Downarrow d, v' \quad (p, s \Downarrow v_s)_{s \leq d} \quad (q[v_s/x], 0 \Downarrow w_s)_{s \leq d} \quad q[v_d/x], t \Downarrow w}{x := p; q, d + t \Downarrow w} \\
(\mathbf{if}_1^e) \frac{p, t \Downarrow v}{\text{if true then } p \text{ else } q, t \Downarrow v} \quad (\mathbf{if}_2^e) \frac{q, t \Downarrow v}{\text{if false then } p \text{ else } q, t \Downarrow v} \quad (\mathbf{pm}^e) \frac{p[v/x, w/y], t \Downarrow u}{\langle x, y \rangle := \langle v, w \rangle; p, t \Downarrow u} \\
(\mathbf{now}^e) \frac{}{\lceil v \rceil, 0 \Downarrow v} \quad (\mathbf{tr}_1^e) \frac{x := s.v \ \& \ w \Downarrow d \quad t < d}{x := s.v \ \& \ w, t \Downarrow v[t/s]} \quad (\mathbf{tr}_2^e) \frac{x := s.v \ \& \ w \Downarrow d, u \quad t \leq d}{x := s.v \ \& \ w, t \Downarrow v[t/s]} \\
(\mathbf{wh}_1^e) \frac{p \Downarrow d \quad p, t \Downarrow w \quad t < d}{x := p \ \text{while} \ v \ \{q\}, t \Downarrow w} \quad (\mathbf{wh}_2^e) \frac{p \Downarrow d, w' \quad p, d \Downarrow w \quad v[w/x] = \text{false}}{x := p \ \text{while} \ v \ \{q\}, d \Downarrow w} \\
(\mathbf{wh}_3^e) \frac{p \Downarrow d, w' \quad p, t \Downarrow w \quad t < d}{x := p \ \text{while} \ v \ \{q\}, t \Downarrow w} \quad (\mathbf{wh}_4^e) \frac{p \Downarrow d, w' \quad p \Downarrow d, w \quad v[w/x] = \text{true} \quad x := q[w/x] \ \text{while} \ v \ \{q\}, t \Downarrow u}{x := p \ \text{while} \ v \ \{q\}, d + t \Downarrow u}
\end{array}$$

Figure 8: Big-step evolution operational semantics

This rule is similar to (\mathbf{seq}_1^d) , but in (\mathbf{seq}_1^e) even if the first computation evaluates to v_t at t , we cannot disregard q and use v_t in the conclusion, because the return type of q need not match the return type of p . The evaluation $q[v_t/x], 0 \Downarrow w_t$ is required to perform the necessary type conversion. Moreover, the rule premise ensures that for every $s \leq t$, $q[v_s/x]$ also yields a value at 0. To see why this is necessary, consider the following instance of $x := p; q$:

$$x := (x := t.t \ \& \ \text{true}); \text{if } x < 1 \ \text{then } (x := 1 \ \& \ \text{false}) \ \text{else } x$$

First observe that for any given time instant $t \geq 0$ the subprogram $x := t.t \ \& \ \text{true}$ evaluates to t , intuitively modelling the passage of time *ad infinitum* and thus producing a trajectory of infinite duration. On the other hand, the subprogram $x := 1 \ \& \ \text{false}$ models non-progressive divergence and *does not* yield a value at any time instant, in particular $q[0/x], 0 \Downarrow v$ for no v . Hence the entire program $x := p; q$ diverges already at 0, as we cannot apply any of the sequential composition rules relative to this time instant. However, $q[1/x], 0 \Downarrow 1$ and therefore if we did not check previous time instants for divergence (using $q[v_s/x], 0 \Downarrow w_s$ for $s \leq 1$) we would obtain $x := p; q, 1 \Downarrow 1$ by the sequential composition rules, meaning that we would not be able to detect divergence of the entire program.

REMARK 3. *The evolution semantics subtly differs from the duration semantics. Specifically, the above example indicates that $p \Downarrow d$ does not necessarily imply that $d = \sup\{t \mid \exists w. p, t \Downarrow w\}$.*

The main subtlety behind our semantics of while-loops via (\mathbf{wh}_1^e) – (\mathbf{wh}_4^e) is that, contrary to standard program semantics, while-loops no longer behave as iterated sequential composition, which would be easily achievable via the rule

$$\frac{(p, s \Downarrow v_s)_{s \leq t} \quad v[v_t/x] = \text{true} \quad (x := q[v_s/x] \ \text{while} \ v \ \{q\}, 0 \Downarrow w_s)_{s \leq t, v[v_s/x] = \text{true}}}{x := p \ \text{while} \ v \ \{q\}, t \Downarrow w_t}$$

instead of (\mathbf{wh}_1^e) and similarly for (\mathbf{wh}_2^e) – (\mathbf{wh}_4^e) . We argue, however, that our rules are more suitable for hybrid programming: the ones corresponding to iterated sequential composition produce undesirable artefacts, e.g. the program

$$x := 0 \ \text{while} \ \text{true} \ \{x := t.(t + x) \ \& \ 1\}$$

would not evaluate under these rules at any time instant (we would not be able to apply any of these rules since at every time instant we would be lacking a terminating condition) and the same would apply to the bouncing ball in Example 3.1 and other systems involving infinite while-loops or Zeno behaviour. Intuitively, the reader may see the adopted rules as the ones corresponding to testing the condition of the while-loop only at the end of the input trajectory whilst assuming that the other points evaluate to false; the rules corresponding to iterated sequential composition would, on the other hand, correspond to testing the condition of the while-loop at *all* points of the input trajectory.

The following lemma is obtained by induction over the derivation of the corresponding computation judgement by the rules in Figure 8.

LEMMA 6.1. *For every closed computation term p , the set*

$$\{t \in \mathbb{R}_+ \mid \exists v. p, t \Downarrow v\}$$

is downward closed.

To relate the operational semantics with its denotational counterpart, recall the hybrid monad \mathbb{H} from our previous work [17] (in a slightly reformulated equivalent form). Intuitively, for every set X , the elements of HX are trajectories in the sense discussed above and Kleisli composition is essentially used for concatenating trajectories whilst simultaneously tracking divergence along the computation. In what follows we use the superscript notation e^t explained in Section 2.

Definition 6.2 (Hybrid monad). The hybrid monad \mathbb{H} is defined as follows. Let

$$\begin{aligned}
HX &= \{\langle cc, d, e : [0, d] \rightarrow X \rangle \mid d \in \mathbb{R}_+\} \cup \\
&\quad \{\langle cd, d, e : [0, d] \rightarrow X \rangle \mid d \in \mathbb{R}_+\} \cup \\
&\quad \{\langle od, d, e : [0, d] \rightarrow X \rangle \mid d \in \bar{\mathbb{R}}_+\},
\end{aligned}$$

i.e. the set HX contains three types of trajectory: *closed convergent* $\langle cc, d, e \rangle$, *closed divergent* $\langle cd, d, e \rangle$ and *open divergent* $\langle od, d, e \rangle$ (notably, there are no “open convergent” ones), e.g., HX contains the *empty trajectory* $\langle od, 0, ! \rangle$, which we denote by \ominus . Given $p = \langle \alpha, d, e \rangle \in HX$, let us write $p_{\text{tt}} = \alpha$, $p_{\text{dr}} = d$, $p_{\text{ev}} = e$, $\text{dom } e = [0, d)$

$$\frac{[\Gamma, t: \mathbb{R} \vdash_v v: A] = h \quad [\Gamma, x: A \vdash_v w: 2] = b \quad \lambda \bar{x}. \sup\{e \in \mathbb{R}_+ \mid \forall t \in [0, e]. b(\bar{x}, h(\bar{x}, t))\} = d}{[\Gamma \vdash_c x := t. v \ \& \ w: A] = \lambda \bar{x}. \langle cc \triangleleft b(\bar{x}, h(\bar{x}, d(\bar{x}))) \triangleright od, d(\bar{x}), \lambda t. h(\bar{x}, t) \rangle}$$

$$\frac{[\Gamma \vdash_c p: A] = h \quad [\Gamma, x: A \vdash_v v: 2] = b \quad [\Gamma, x: A \vdash_c q: A] = l}{[\Gamma \vdash_c x := p \ \text{while} \ v \ \{q\}: A] = \lambda \bar{x}. ((\lambda \langle x, c \rangle. (H \text{inr})(\kappa l(\bar{x}, x)) \triangleleft b(\bar{x}, x) \wedge c \triangleright \eta(\text{inl } x))^\dagger)^\star(\kappa(h(\bar{x})))}$$

Figure 9: Denotational evolution semantics

if $\alpha = od$ and $\text{dom } e = [0, d]$ otherwise. For a map $f: X \rightarrow HY$ we will abbreviate the notation $(f(x))_{\text{tt}}$ to $f_{\text{tt}}(x)$, and similarly for the other cases, namely $(f(x))_{\text{dr}}$, $(f(x))_{\text{ev}}$ and $(f(x))^t$. The monad structure of \mathbb{H} is then given in the following way: $\eta(x) = \langle cc, 0, \lambda t. x \rangle$; for $f: X \rightarrow HY$, $\langle \alpha, d, e \rangle \in HX$, let

$$D = \bigcup \{ [0, t] \subseteq \text{dom } e \mid \forall s \in [0, t]. f(e^s) \neq \ominus \},$$

$d' = \sup D$. Then $f^\star(\alpha, d, e)$ is defined by the clauses:

$$\begin{aligned} f^\star(cc, d, e) &= \langle f_{\text{tt}}(e^d), d + f_{\text{dr}}(e^d), \\ &\quad \lambda t. f_{\text{ev}}^0(e^t) \triangleleft t < d \triangleright f_{\text{ev}}^{t-d}(e^d) \rangle \quad (D = [0, d]) \\ f^\star(cd, d, e) &= \langle cd, d, \lambda t. f_{\text{ev}}^0(e^t) \rangle \quad (D = [0, d]) \\ f^\star(\alpha, d, e) &= \langle cd, d', \lambda t. f_{\text{ev}}^0(e^t) \rangle \quad (D = [0, d'], d' < d) \\ f^\star(\alpha, d, e) &= \langle od, d', \lambda t. f_{\text{ev}}^0(e^t) \rangle \quad (D = [0, d'], d' \leq d) \end{aligned}$$

Intuitively, only the first clause for $f^\star(\alpha, d, e)$ describes a successful ‘concatenation’ scenario, which assumes that the argument trajectory is closed and additionally ensures that $f(e^s)$ does not yield divergence along the run of $\langle cc, d, e \rangle$. The remaining clauses exhaustively cover divergence scenarios, caused either by $f(e^s)$ or by the argument trajectory. As shown in [17], \mathbb{H} is an Elgot monad. We thus reuse the rules from Figure 7 to define the semantics over \mathbb{H} by replacing Q with H throughout, except for the rules for **(tr)** and **(wh)** which are overridden by those in Figure 9. To cope with the non-standard behaviour of while-loops discussed above, we call on an auxiliary natural transformation $\kappa: H \rightarrow H(- \times 2)$, appending to every point of the trajectory a Boolean flag signalling whether the current point is the endpoint, formally:

$$\kappa(\alpha, d, e) = \langle \alpha, d, u \rangle, \quad u^t = \begin{cases} \langle e^t, \top \rangle & \text{if } \alpha = cc, t = d, \\ \langle e^t, \perp \rangle & \text{otherwise.} \end{cases}$$

Finally, we obtain our main result.

THEOREM 6.3 (SOUNDNESS AND ADEQUACY). *Given $- \vdash_c p: A$,*

- (1) $p, t \Downarrow v$ iff $\llbracket - \vdash_c p: A \rrbracket = \langle \alpha, d, e \rangle, t \leq d$ and $e^t = v$;
- (2) $p, d \Downarrow v$ and $p \Downarrow d, w$ iff $v = w, \llbracket - \vdash_c p: A \rrbracket = \langle cc, d, e \rangle$ and $e^d = v$.

The first clause ensures that the correspondence $t \mapsto v_t$ generated by the judgements $p, t \Downarrow v_t$ yields a trajectory that agrees with the denotational semantics previously presented. The second clause is needed to relate the duration and evolution semantics: both must agree in the evaluation of the *last point* of the trajectory produced by a program p , and naturally both must agree with the corresponding denotational semantics.

The theorem follows from a sequence of lemmas, which we present next. In the rest of the section, we subscript the semantic brackets with \mathbb{Q} and \mathbb{H} to refer to duration semantics and to

evolution semantics correspondingly. The first lemma provides a technical characterization of iterations occurring as the semantics of while-loops.

LEMMA 6.4. *Let $f: X \rightarrow H(Y + X)$ have the property*

$$\forall x \in X. (\exists y \in X. f_{\text{ev}}^t(x) = \text{inr } y) \Rightarrow f_{\text{tt}}(x) = cc \wedge f_{\text{dr}}(x) = t. \quad (3)$$

We define $f_i: X \rightarrow H(Y + X)$ by induction as follows: $f_0 = \eta \text{inr}$, $f_{i+1} = [\eta \text{inl}, f_i]^\star f$. Let $x \in X$, and suppose that $f^\dagger(x) = \langle \alpha, d, e \rangle$.

- (1) *If $t < d$ then there exists $n \in \mathbb{N}$ such that $t < (f_n)_{\text{dr}}(x)$ and $(f_n)_{\text{ev}}^t(x) = \text{inl } e^t$.*
- (2) *If $\alpha \neq od$ then there exists $n \in \mathbb{N}$ such that $d = (f_n)_{\text{dr}}(x)$ and $(f_n)_{\text{ev}}^d(x) = \text{inl } e^d$.*

PROOF. We rely on the fact that \mathbb{H} is characterized as an iteration-congruent retract of a monad $\mathbb{H}_0\mathbb{M}$ obtained by composing \mathbb{H}_0 , an iteration-free version of \mathbb{H} , with the *maybe-monad* \mathbb{M} (with $MX = X+1$) [17]. That is, there is a monad morphism $\rho: \mathbb{H}_0\mathbb{M} \rightarrow \mathbb{H}$, whose components ρ_X come with right inverses v_X and ρ preserves iteration as follows: $\rho f^\ddagger = (\rho f)^\dagger$. Here, by $(-)^{\ddagger}$ we refer to the iteration of $\mathbb{H}_0\mathbb{M}$, which is suitably characterized as the least solution of the fixpoint law. For the sake of the present argument it suffices to know that H_0MX is obtained from HX by allowing the trajectories to be partial functions and by imposing the the following constraints:

- $\langle cc, d, e \rangle \in H_0MX$ implies that e^d is defined;
- closed divergent trajectories are not in H_0MX .

The natural transformation $v: H \rightarrow H_0M$ sends $\langle cc, d, e \rangle \in HX$ to $\langle cc, d, e \rangle \in H_0MX$ and $\langle \alpha, d, e \rangle \in HX$ with $\alpha \in \{cd, od\}$ to $\langle od, \infty, e' \rangle \in H_0MX$ where e' is the extension of e to \mathbb{R}_+ with undefined elements. Conversely, $\rho(\alpha, d, e)$ is $\langle \alpha, d, e \rangle$ for total e and $\rho(\alpha, d, e) = \langle \alpha', d', e' \rangle$ for partial e , in which case e' is a restriction of e to the largest downward closed subset of the domain of definiteness of e and d' and $\alpha \in \{cd, od\}$ are selected accordingly.

Let $g = vf: X \rightarrow H_0M(Y + X)$. For every i , let $g^{(i)}: X \rightarrow H_0MY$ be defined as follows: $g^{(0)} = \ominus$ (the empty trajectory) and $g^{(i+1)} = [\eta, g^{(i)}]^\star g$. We use the following property of $\mathbb{H}_0\mathbb{M}$ [17, Lemma 25]:

$$\forall x \in X. g^{\ddagger}(x) = \langle \alpha, d, e \rangle \wedge e^t \in Y \Rightarrow \exists n. (g^{(n)})_{\text{ev}}^t(x) = \text{inl } e^t \quad (4)$$

for every $t \leq d$ for which e^t is defined. Let us define $g_0 = \eta \text{inr}$, $g_{i+1} = [\eta \text{inl}, g_i]^\star g$ and note that, by induction, for every i , $g^{(i)} = [\eta, \ominus]^\star g_i$. Therefore we can reformulate (4) as follows:

$$\forall x \in X. g^{\ddagger}(x) = \langle \alpha, d, e \rangle \wedge e^t \in Y \Rightarrow \exists n. (g_n)_{\text{ev}}^t(x) = \text{inl } e^t. \quad (5)$$

In order to obtain the first clause of the lemma, suppose that $f^\dagger(x) = \langle \alpha, d, e \rangle$ and $t < d$. Now $f^\dagger(x) = \rho g^{\ddagger}(x) = \langle \alpha, d, e \rangle$ and therefore $g^{\ddagger}(x) = \langle \alpha', d', e' \rangle$ with suitable α', d', e' and $(e')^t = e^t$ because e' is at least as defined as e . By (5), for some n , $(g_n)_{\text{ev}}^t(x) = \text{inl } e^t$.

Note that by definition g satisfies (3) and for every $y \in X$ the trajectory $g_{\text{ev}}(y)$ is total. It follows by induction that the same is true for g_n , hence $g_n(x) = v(f_n(x))$, in particular, $t < (f_n)_{\text{dr}}(x)$ and $(f_n)_{\text{ev}}^t(x) = \text{inl } e^t$. The second clause is shown analogously. \square

Next, we check that the duration semantics and the evolution semantics agree in the following sense (cf. Remark 3).

LEMMA 6.5. *Given a computation judgement $\Gamma \vdash_c p: A$, let $\bar{v} \in \llbracket \Gamma \rrbracket$. Suppose that $\llbracket \Gamma \vdash_c p: A \rrbracket_{\mathbb{H}}(\bar{v}) = \langle \alpha, d, e \rangle$ and $\llbracket \Gamma \vdash_c p: A \rrbracket_{\mathbb{Q}}(\bar{v}) = \langle d', v \rangle$. Then $\alpha = \text{cc}$ iff $d = d'$ and in either case $e^d = v$.*

PROOF SKETCH. The proof runs by induction over the structure of p . We restrict to the following three representative cases.

- $p = (x := q; r)$. Let $f = \llbracket \Gamma \vdash_c q: B \rrbracket_{\mathbb{H}}$, $g = \llbracket \Gamma, x: B \vdash_c r: A \rrbracket_{\mathbb{H}}$, $\hat{f} = \llbracket \Gamma \vdash_c q: B \rrbracket_{\mathbb{Q}}$, $\hat{g} = \llbracket \Gamma, x: B \vdash_c r: A \rrbracket_{\mathbb{Q}}$. Suppose that $\alpha = \text{cc}$. Then $\llbracket \Gamma \vdash_c p: A \rrbracket_{\mathbb{H}}(\bar{v}) = g^* \tau(\bar{v}, f(\bar{v})) = \langle \text{cc}, d, e \rangle$, which by definition means that

$$f(\bar{v}) = \langle \text{cc}, d_1, e_1 \rangle, \quad g(\bar{v}, e_1^{d_1}) = \langle \text{cc}, d_2, e_2 \rangle, \quad d = d_1 + d_2,$$

and, analogously

$$\hat{f}(\bar{v}) = \langle d'_1, v' \rangle, \quad \hat{g}(\bar{v}, v') = \langle d'_2, v \rangle, \quad d' = d'_1 + d'_2.$$

By induction, $d_1 = d'_1$ and $e_1^{d_1} = v'$. Hence, again by induction, $d_2 = d'_2$ and $e_2^{d_2} = v$. This implies $d = d'$ and $e^d = e_2^{d_2} = v$. By reversing this argument we also obtain the implication in the right-to-left direction.

- $p = (x := t.v \ \& \ w)$. By definition,

$$\llbracket \Gamma \vdash_c p: A \rrbracket_{\mathbb{H}}(\bar{v}) = \langle \text{cc}, u(\bar{v}), \lambda t. h(\bar{v}, t) \rangle \triangleleft b(\bar{v}, h(\bar{v}, u(\bar{v}))) \triangleright \langle \text{od}, u(\bar{v}), \lambda t. h(\bar{v}, t) \rangle,$$

$$\llbracket \Gamma \vdash_c p: A \rrbracket_{\mathbb{Q}}(\bar{v}) = \langle u(\bar{v}), h(\bar{v}, u(\bar{v})) \rangle \triangleleft b(\bar{v}, h(\bar{v}, u(\bar{v}))) \triangleright u(\bar{v})$$

where $h = \llbracket \Gamma, t: \mathbb{R} \vdash_v v: A \rrbracket$ and $b = \llbracket \Gamma, x: A \vdash_v w: 2 \rrbracket$, $u = \lambda \bar{x}. \sup\{e \in \mathbb{R}_+ \mid \forall t \in [0, e]. b(\bar{x}, h(\bar{x}, t))\}$. The assumption implies $b(\bar{v}, h(\bar{v}, u(\bar{v}))) = \top$, hence we reduce to

$$\llbracket \Gamma \vdash_c p: A \rrbracket_{\mathbb{H}}(\bar{v}) = \langle \text{cc}, u(\bar{v}), \lambda t. h(\bar{v}, t) \rangle,$$

$$\llbracket \Gamma \vdash_c p: A \rrbracket_{\mathbb{Q}}(\bar{v}) = \langle u(\bar{v}), h(\bar{v}, u(\bar{v})) \rangle$$

and the claim of the lemma holds trivially.

- $p = (x := q \ \text{while} \ v \ \{r\})$. By definition,

$$\llbracket \Gamma \vdash_c p: A \rrbracket_{\mathbb{H}}(\bar{v}) = ((\lambda x. c). (H \text{ inr})(\kappa l(\bar{v}, x)) \triangleleft b(\bar{v}, x) \wedge c \triangleright \eta(\text{inl } x))^{\dagger} \star (\kappa h(\bar{v})),$$

$$\llbracket \Gamma \vdash_c p: A \rrbracket_{\mathbb{Q}}(\bar{v}) = ((\lambda x. (Q \text{ inr})(\hat{l}(\bar{v}, x)) \triangleleft b(\bar{v}, x) \triangleright \eta(\text{inl } x))^{\dagger} \star (\hat{h}(\bar{v})))$$

where $b = \llbracket \Gamma, x: A \vdash_v v: 2 \rrbracket$, and

$$h = \llbracket \Gamma \vdash_c q: A \rrbracket_{\mathbb{H}}, \quad l = \llbracket \Gamma, x: A \vdash_c r: A \rrbracket_{\mathbb{H}},$$

$$\hat{h} = \llbracket \Gamma \vdash_c q: A \rrbracket_{\mathbb{Q}}, \quad \hat{l} = \llbracket \Gamma, x: A \vdash_c r: A \rrbracket_{\mathbb{Q}}.$$

Suppose that $\llbracket \Gamma \vdash_c q: A \rrbracket_{\mathbb{H}}(\bar{v}) = \langle \text{cc}, d, e \rangle$. Then, by definition of \mathbb{H} , $d = d_0 + d_{\star}$ where

$$\langle \text{cc}, d_0, e_0 \rangle = h(\bar{v}),$$

$$\langle \text{cc}, d_{\star}, e_{\star} \rangle =$$

$$(\lambda x. c). (H \text{ inr})(\kappa l(\bar{v}, x)) \triangleleft b(\bar{v}, x) \wedge c \triangleright \eta(\text{inl } x)^{\dagger} (e_0^{d_0}, \top).$$

Consider the sequence

$$\langle \text{cc}, d_0, e_0 \rangle, \langle \text{cc}, d_1, e_1 \rangle, \dots \quad (6)$$

formed as follows: $\langle \text{cc}, d_{i+1}, e_{i+1} \rangle = l(\bar{v}, e_i^{d_i})$ if $b(\bar{v}, e_i^{d_i})$. That is, every triple $\langle \text{cc}, d_{i+1}, e_{i+1} \rangle$ is obtained by applying the above expression under dagger to $\langle e_i^{d_i}, \top \rangle$ as long as $b(\bar{v}, e_i^{d_i})$ is true. Note that this process cannot produce triples with the first element different than cc , because this would mean that the loop diverges after finitely many iterations, returning a triple different from $\langle \text{cc}, d_{\star}, e_{\star} \rangle$. By Lemma 6.4 (2), the sequence (6) is necessarily finite. Hence, by induction hypothesis $\llbracket \Gamma, x: A \vdash_c r: A \rrbracket_{\mathbb{Q}}(\bar{v}, e_i^{d_i}) = \langle d_{i+1}, e_{i+1}^{d_{i+1}} \rangle$ for every i , from which we obtain $\llbracket \Gamma \vdash_c p: A \rrbracket_{\mathbb{Q}}(\bar{v}) = \langle d, e^d \rangle$, as desired.

For the converse, suppose that $\llbracket \Gamma \vdash_c p: A \rrbracket_{\mathbb{Q}}(\bar{v}) = \langle d, v \rangle$. By definition of iteration in \mathbb{Q} , this means that the loop in $\llbracket \Gamma \vdash_c p: A \rrbracket_{\mathbb{Q}}(\bar{v})$ is unfolded finitely many times, i.e. $\langle d_0, v_0 \rangle = \hat{h}(\bar{v})$, $\langle d_1, v_1 \rangle = \hat{l}(\bar{v}, v_0), \dots, \langle d_n, v_n \rangle = \hat{l}(\bar{v}, v_{n-1})$ and $b(\bar{v}, v_0) = \top, \dots, b(\bar{v}, v_{n-1}) = \top, b(\bar{v}, v_0) = \perp$ for suitable d_i, v_i and $d = d_0 + \dots + d_n, v = v_n$. By induction hypothesis, $\llbracket \Gamma \vdash_c p: A \rrbracket_{\mathbb{H}}(\bar{v}) = \langle \text{cc}, d_0, e_0 \rangle$, $\llbracket \Gamma, x: A \vdash_c q: A \rrbracket_{\mathbb{H}}(\bar{v}, v_i) = \langle \text{cc}, d_{i+1}, e_{i+1} \rangle$ for $i = 1, \dots, n$ and $e_i^{d_i} = v_i$ for every $i = 0, \dots, n$. Using the above expression for $\llbracket \Gamma \vdash_c p: A \rrbracket_{\mathbb{Q}}(\bar{v})$ and the assumption that $\llbracket \Gamma \vdash_c p: A \rrbracket_{\mathbb{H}}(\bar{v}) = \langle \alpha, d, e \rangle$, we obtain that $\alpha = \text{cc}$. \square

The following lemma essentially captures the soundness direction of Theorem 6.3.

LEMMA 6.6. *Given $\vdash_c p: A$,*

- (1) *if $p, t \Downarrow v$ then $\llbracket \vdash_c p: A \rrbracket_{\mathbb{H}} = \langle \alpha, d, e \rangle$, $t \leq d$ and $e^t = v$;*
- (2) *if $p, d \Downarrow v$ and $p \Downarrow d, w$ then $v = w$, $\llbracket \vdash_c p: A \rrbracket_{\mathbb{H}} = \langle \text{cc}, d, e \rangle$ and $e^d = v$.*

PROOF. First, let us argue that for a fixed $\vdash_c p: A$, (1) implies (2). Indeed, $p, d \Downarrow v$ by the first clause implies that $\llbracket \vdash_c p: A \rrbracket_{\mathbb{H}} = \langle \alpha, d, e \rangle$, $e^d = v$ and by Theorem 5.8, $\llbracket \vdash_c p: A \rrbracket_{\mathbb{Q}} = \langle d, w \rangle$. By Lemma 6.5, $e^d = w = v$ and $\alpha = \text{cc}$.

The proof of (1) is now obtained analogously to the proof of Theorem 5.8, by induction over the derivation $p, t \Downarrow v$ in the proof system of Figure 8. We occasionally need to call both (1) and (2) in the induction step, but, as we argued (1) implies (2) for every specific p . Consider, e.g. the rule

$$(\text{seq}_2^c) \frac{p \Downarrow d, v' \quad (p, s \Downarrow v_s)_{s \leq d} \quad (q[v_s/x], 0 \Downarrow w_s)_{s \leq d} \quad q[v_d/x], t \Downarrow w}{x := p; q, d + t \Downarrow w}$$

in detail. By induction hypothesis, $\llbracket \vdash_c p: A \rrbracket_{\mathbb{H}} = \langle \text{cc}, d, e \rangle$, $e^d = v_d$, $\llbracket \vdash_c q[v_d/x]: B \rrbracket_{\mathbb{H}} = \langle \alpha, d_{\star}, e_{\star} \rangle$, $t \leq d_{\star}$, $e_{\star}^t = w$. Now, by definition, and using Lemma 6.1,

$$\llbracket \vdash_c x := p; q: A \rrbracket_{\mathbb{H}}$$

$$= \langle f_{\text{tt}}(e^d), d + f_{\text{dr}}(e^d), \lambda s. f_{\text{ev}}^0(e^s) \triangleleft s < d \triangleright f_{\text{ev}}^{s-d}(e^d) \rangle$$

$$= \langle f_{\text{tt}}(v_d), d + f_{\text{dr}}(v_d), \lambda s. f_{\text{ev}}^0(v_s) \triangleleft s < d \triangleright f_{\text{ev}}^{s-d}(v_d) \rangle$$

where $f = \llbracket x: B \vdash_c q: A \rrbracket_{\mathbb{H}}$, and therefore $d + t \leq d + d_{\star} = d + f_{\text{dr}}(v_d)$ and

$$f_{\text{ev}}^0(v_{d+t}) \triangleleft d + t < d \triangleright f_{\text{ev}}^{d+t-d}(v_d) = f_{\text{ev}}^t(v_d) = e_{\star}^t = w,$$

as desired. \square

The following lemma essentially captures the adequacy direction of Theorem 6.3.

LEMMA 6.7. *If $\llbracket - \vdash_c p : A \rrbracket_{\mathbb{H}} = \langle \alpha, d, e \rangle$ and $t \leq d$ then $p, t \Downarrow v$ for some v .*

PROOF SKETCH. The proof is analogous to the corresponding fragment of the proof of Theorem 5.8. Let us consider the case of while-loops, which is the trickiest one. That is, we have to show that $\llbracket - \vdash_c x := p \text{ while } b \{q\} : A \rrbracket_{\mathbb{H}} = \langle \alpha, d, e \rangle$ and $t \leq d$ imply that $x := p \text{ while } b \{q\}, t \Downarrow v$ for some v . By expanding the assumption we obtain

$$\langle \alpha, d, e \rangle = (\lambda \langle x, c \rangle. (H \text{ inr})(\kappa(l(x))) \triangleleft b(x) \wedge c \triangleright \eta(\text{inl } x))^{\dagger} \star (\kappa(\alpha_0, d_0, e_0))$$

where $b = \llbracket x : A \vdash_v v : 2 \rrbracket$, $\langle \alpha_0, d_0, v_0 \rangle = \llbracket - \vdash_c p : A \rrbracket_{\mathbb{H}}$ and $l = \llbracket x : A \vdash_c q : A \rrbracket_{\mathbb{H}}$. If $\alpha_0 = \text{od}$ or $\alpha_0 = \text{cd}$, the above equation yields $\alpha_0 = \alpha$, $d = d_0$ and $e = e_0$ and we obtain the requisite judgement using the induction hypothesis either by **(wh₁^c)** or by **(wh₂^c)**. The same considerations apply if $t < d_0$. We proceed under the assumption that $\alpha_0 = \text{cc}$ and $t \geq d_0$. Consider the sequence

$$\langle \text{cc}, d_0, e_0 \rangle, \langle \text{cc}, d_1, e_1 \rangle, \dots \quad (7)$$

iteratively constructed as follows: d_{i+1} and e_{i+1} are defined as long as $\langle \text{cc}, d_{i+1}, e_{i+1} \rangle = l(e_i^{d_i})$ and $b(e_i^{d_i})$ is true. If any of the latter conditions eventually fails, the sequence (7) terminates resulting in $d = d_0 + \dots + d_n$ for some t . We then construct the requisite derivation of $x := p \text{ while } b \{q\}, t \Downarrow v$ by calling the induction hypothesis. If the sequence (7) is infinite, still, by Lemma 6.4 (1), for some n , $d_0 + \dots + d_n \leq t < d_0 + \dots + d_{n+1}$ and $e^t = e_n^{t-d_0-\dots-d_n}$. Again, by induction, we can construct a derivation of the judgement $x := p \text{ while } b \{q\}, t \Downarrow e_n^{t-d_0-\dots-d_n}$. \square

Finally, we can prove the soundness and adequacy theorem that was previously mentioned.

PROOF (THEOREM 6.3). The Lemmas 6.6, 6.7 and 6.5 jointly imply the theorem as follows. The left-to-right directions for both clauses are already in Lemma 6.6. For the right-to-left direction of the first clause, Lemma 6.7 produces some value v , which, again by the soundness direction must be the one for which $e^t = v$. For the right-to-left direction of the second clause we additionally use Lemma 6.5. \square

7 CONCLUSIONS AND FURTHER WORK

Our present work is a result of an ongoing effort to establish solid semantic foundations for hybrid computation. More specifically, here we complement our previous work on denotational models [16, 17, 34] in terms of *hybrid monads*, with a corresponding operational semantics and connect both styles of semantics by a soundness and adequacy theorem. The central ingredient of our framework is a hybrid, call-by-value while-language HYBCORE, which we put forward as syntactic means for capturing the essence of hybrid computation, subsequently study it, and use as basis of future, more complex hybrid programming languages. The task of formulating an adequate operational semantics turned out to require a sophisticated route via an auxiliary lightweight duration semantics, and we regard the fact of success, i.e. the fact that

the term “adequate operational semantics” can actually be sensibly interpreted in the hybrid setting, as a striking outcome of this work.

HYBCORE provides a minimal framework combining the basic and uncontroversial features of hybrid computation with clear and principled semantic foundations. We plan to use it both as a stepping stone and as a yardstick in further work. The fact that HYBCORE purposefully combines the classical view of (instantaneous) computations – which either succeed immediately or silently diverge (e.g. variable assignments in a loop) – and processes extended over real-time, makes the operational semantics of HYBCORE particularly distinct, specifically, the rules generally require *continuum-size* numbers of premises, which is needed to ensure the integrity of the resulting trajectories. This kind of complexity vanishes when restricting to progressive semantics, which is obtained by forbidding empty trajectories. The submonad \mathbb{H}_+ of \mathbb{H} that arises from this restriction, was studied in [16] and enjoys better properties than \mathbb{H} ; we expect our adequacy result to restrict accordingly. This task is however not entirely trivial, as it requires a considerable adaptation of the language to keep track of progressiveness of terms, yet a systematic approach to this issue was proposed recently [18].

As indicated in the introduction, the use of monads gives access to various generic scenarios for combining hybridness with other effects, specifically via universal constructions and monad transformers. One generic construction that can be applied to \mathbb{H} is the *generalized coalgebraic resumption monad transformer* [19] sending an endofunctor T to the coalgebra $T_F = \nu \gamma. T(- + F\gamma)$ for a given endofunctor F , which can be chosen suitably for modelling *interactive/concurrent* features, e.g. $F = A \times -$ corresponds to automata or process algebra-style actions ranging over A . By the abstract results in [19] for an Elgot monad \mathbb{T} , T_F canonically extends to an Elgot monad \mathbb{T}_F , which is indeed the case for $\mathbb{T} = \mathbb{H}$. A disciplined way of adding further effects to HYBCORE is by resorting to Plotkin and Power’s *generic effects* [37]. E.g. for binary non-determinism, we would need a coin-tossing primitive $\Gamma \vdash_c \text{toss}() : 2$ for choosing a control branch non-deterministically, yielding a non-deterministic choice operator in the following way (a similar approach applies e.g. to probabilistic choice):

$$p + q = (b := \text{toss}()); \text{ if } b \text{ then } p \text{ else } q).$$

Denotationally, in order to interpret such extensions of HYBCORE we need to modify \mathbb{H} by applying suitable monad transformers, in particular, we plan to extend previous work on combining iteration-free versions of \mathbb{H} with other monads [12]. Our commitment to the language of categorical constructions raises hopes that the presented developments can be carried over to categories other than Set and more suitable for analysing topological aspects of hybrid dynamics, such as *stability* of hybrid behaviour under input perturbations. E.g. the construction of the duration monad as a quotient of the corresponding layered duration monad can be instantly reproduced in the category Top of topological spaces, therefore inducing a necessary topologization in a canonical way. It remains an important goal of further work to provide an analogous treatment for the hybrid monad \mathbb{H} , possibly by introducing a *layered hybrid monad* whose quotient would be \mathbb{H} . Our long-term goal is to extend HYBCORE to a higher-order hybrid language with general recursion.
